The aureomycin was stopped, as it was thought to have had little effect, and sulphadimidine was tried. Within two days it became obvious that the ulceration had been controlled by the aureomycin, since the indurated area rapidly extended and the ulcer spread to the left ala nasi. Aureomycin, 250 mg. three-hourly, was recommenced on

FIG. 1.—The condition on September 21.

FIG. 2.—Photograph taken on September 28.

FIG. 3.—Photograph taken on December 27.

September 19, the dosage being raised to 500 mg. three-hourly two days later, when it was found that the serum aureomycin was only 0.75 μ g. per ml. Within twelve hours the crusts began to separate and the induration and oedema lessened (Fig. 1). On September 25 the serum aureomycin had risen to 2 μ g. per ml., but the most recent culture taken from beneath the crust still revealed a *Staph. pyogenes* which was sensitive to 1.5 μ g. of aureomycin. On the 26th the aureomycin was increased to 750 mg. three-hourly, and a solution of aureomycin in water, 1,000

μ g. per ml., was applied on gauze to the surface of the ulcer. Despite the high dosage the serum aureomycin did not rise above 2 μ g. per ml. The ulcerated area had by now improved, since the main slough was separating and the inside of the nose appeared healed, but there was still slow extension down the lip and over the ala nasi (Fig. 2).

By October 17 the condition appeared stationary, and, in view of the greater ease with which high levels could be obtained in the serum, treatment was changed to chloramphenicol, 1 g. followed by 0.5 g. three-hourly. During the few hours at the change-over of treatment the left side of the face became more oedematous, closing the left eye, and the edge of the ulcer became more red and painful. Within 12 hours these signs had subsided and the ulcer looked more healthy than at any time previously. A further exposure to x rays, 100 r, was given on October 24. Next day the serum chloramphenicol was 25 μ g. per ml. During the next few days the oedema and induration of the face subsided and the ulcer healed steadily. Numerous cultures taken from the nose and surface of the ulcer were sterile. By November 16 only one small scab remained. The chloramphenicol was stopped and the patient was discharged home on the 18th, but was kept under observation as an out-patient.

On November 28, after a common cold, the oedema of the left side of the face returned and induration reappeared at the edge of the scar, together with several superficial pustules. Chloramphenicol, 0.5 g. six-hourly, was started at once. A culture taken from the pustules before treatment was begun showed *Staph. pyogenes* which was penicillin-sensitive, but in view of its previous success chloramphenicol was continued. The slight recurrence was cleared within a week, but the drug was given until January 4, 1951. Since then she has remained well and is not grossly disfigured, though the scar has retracted her upper lip (Fig. 3). It is noteworthy that throughout the long illness her temperature never rose above normal and her white cell count was never above 6,000 per c.mm., also that no toxic effects arose from the high dosage of antibiotics which were given over a long period.

Discussion

Sensitivity to Antibiotics.—The estimations of the sensitivity of the organisms to aureomycin and to chloramphenicol were carried out by inoculating serial dilutions of the standard antibiotics in phenol-red-serum water (May *et al.*, 1947) with a 1/10 dilution of a 24-hour broth culture. The tube which just did not show growth was taken to be the least concentration of the antibiotic to which the organism was sensitive. The antibiotic content of the patient's serum was estimated by comparing serial dilutions in phenol-red-serum water with standard dilutions of the antibiotic, using *Bacillus cereus* (Lederer No. 5) as the inoculating organism. In view of the instability of aureomycin in a solution of pH 7.6 at 37° C. it may be that the organisms tested were actually more sensitive than the *in vitro* tests showed. However, this was not borne out by the progress of the case under treatment.

Diagnosis

The clinical features of the present case correspond very closely with those previously published under the names of malignant granuloma of the nose, progressive lethal granulomatous ulceration of the nose, and chronic infectious granuloma of the nose. Photographs of Lierle's (1942) case are so similar to our case that they could easily be confused. It was perhaps fortunate that the patient, being a hospital employee, was seen at a very early stage in the disease, when it appeared to be an infection and not a neoplasm, such as might have been diagnosed if the ulcer had penetrated the tissues more deeply. For that reason, and the risk of extending the infection, a biopsy was not performed.

Aetiology

The pathological changes in all the cases previously described have been those of areas of necrosis surrounded by a zone of new granulation tissue and a zone of infiltration with inflammatory cells, mainly lymphocytes, with an occasional giant cell. Hargrove *et al.* drew attention to a state of obliterative arteritis affecting the blood vessels beyond the infiltrated area. Stewart (1933b) reviews 10 cases, and in summing up the findings says: "The disease is not one of formation but of destruction." He also draws attention to the complete absence of resistance of the patient to infection. The course of the present case excluded a malignant growth, since the radiotherapy given was not of such dosage as to control a neoplasm. The disease must then be ascribed either to an organism not yet discovered or to an unusual tissue response to infection with known pyogenic organisms.

We believe that the staphylococcus which was found so consistently in the lesion in our case played a prominent part in the cause of the ulceration and was not just a secondary invader. The spread of infection was controlled by aureomycin—rapid extension occurring when the antibiotic was stopped—and during the change-over of treatment to chloramphenicol. When adequate doses of chloramphenicol were given the staphylococcus could not be isolated from the lesion, and healing continued. The slight recurrence was due to infection with a staphylococcus of different sensitivity to antibiotics, and was therefore presumably a fresh strain. This suggests that the granulomatous overgrowth is a non-specific reaction to staphylococcal infection and not to any one particular strain of the organism. Such a theory would explain the occurrence of two attacks separated by an interval of 23 years, as occurred in Hoover's Case 3 and in Lierle's case when a recurrence was precipitated by a blow on the nose. Reinfection with a rare organism would be too great a coincidence. The absence of regional lymph-node enlargement, of leucocytosis, and, in our case, of pyrexia, suggests a failure of the defence mechanism.

That staphylococci are capable of producing indolent inflammatory lesions of the skin has long been known—this is perhaps best characterized by acrodermatitis perstans of Hallopeau; and the common pyogenic granuloma is a good example of exuberant granulation tissue stimulated by staphylococcal infection. Of 17 published cases in which bacteriological findings are given, staphylococci either alone or with streptococci were found in 15: although staphylococci can be isolated by nasal swab from many people, this finding is compatible with our theory.

Summary

A case of progressive granulomatous ulceration of the nose and face is described.

A penicillin-resistant *Staph. pyogenes* was isolated from the lesion, at first in combination with a haemolytic streptococcus and an avirulent corynebacterium; later the staphylococcus was obtained in pure culture.

Aureomycin prevented an extension of the infection, but a staphylococcus sensitive to the drug *in vitro* could still be recovered from the lesion.

Chloramphenicol produced a gradual but complete recovery, with coincident disappearance of the staphylococcus from the ulcer.

The aetiology of the condition is discussed and the suggestion put forward that it is a non-specific but unusual response to staphylococcal infection.

It is suggested that chloramphenicol may be as good as, if not superior to, aureomycin in the treatment of staphylococcal infections.

We should like to express our thanks to Mr. J. H. Cobb for his co-operation and for drawing our attention to the previously published work on the subject.

PURPURA AND PANCYTOPENIA COMPLICATING ARSENOTHERAPY

BY

M. G. NELSON, M.D., M.R.C.P., M.R.C.P.I.
D.T.M.&H.

Clinical Pathologist, Royal Victoria Hospital, Belfast

Purpura and other blood disorders are rare complications of the treatment of syphilis by organic arsenicals. The possibility that these drugs might be responsible for the purpuric manifestations was suggested by Labbé and Langlois (1919) only nine years after their introduction. The first to be incriminated was arsphenamine, and Loveman (1932) described 14 cases in the literature up to that date, and added one case of his own which showed a pancytopenia, with thrombocytopenic purpura, agranulocytosis, and aplastic anaemia. Falconer and Epstein (1940) described eight of their own cases of purpura occurring during arsenical treatment. All the organic arsenicals employed in the treatment of syphilis have been suspect, but neoarsphenamine has been involved more often than any other—in part, perhaps, because of its more widespread use. "Mapharsen" was introduced in 1936, but purpura associated with this form of arsenical has been relatively uncommon. However, Wintrobe (1946) mentions having seen three cases, and one further case was reported by Schwartz and Vonder Heide (1945).

Though these complications of arsenotherapy are rare, four cases were admitted to the Royal Victoria Hospital during a period of nine months. These cases had a similar clinical picture but somewhat dissimilar haematological findings, and three ended fatally. These cases are thought worthy of record.

Case 1

A married woman aged 30, with one child aged 8, was first seen by her doctor in July, 1948, having a sore on the vulva. This was treated with penicillin ointment locally and a sulphonamide by mouth; her blood was serologically positive for syphilis. She was referred to the V.D. out-patient department, but refused examination. She was seen again in August, when she had developed a copper-coloured rash, which had been noticed for one day. It was distributed over the chest and abdomen, and to a less extent on the arms and inner sides of the thighs. The cervical and inguinal lymph nodes were enlarged. A small ulcer present on the vulva showed *Treponema pallidum* on dark-ground examination. Her Kahn reaction was + + + +, W.R. + +, and Dreyer reading 108. She denied extramarital intercourse, but stated that her husband, who was in the Army, had been home on leave in May of that year.

Penicillin treatment, 3,000,000 units in 10 days, was given. This was followed by courses of combined bismuth and arsenic injections. Over a period of somewhat less than a year she received 3 g. of bismuth, 0.86 g. of mapharsen, and 7.2 g. of neoarsphenamine. Serological tests for syphilis were negative in January, 1949. During the third course of

arsenic and bismuth, in March, 1949, she noticed a dark rash on her body and bleeding from her gums, and she was immediately admitted to the hospital.

On examination she was seen to be a somewhat pale woman of average height and normal build. An extensive petechial rash, almost confluent, was scattered over her face, arms, and legs, being most extensive on the limbs. She was bleeding from her gum margins, and numerous blood-filled vesicles were seen in her mouth. There was no haemoptysis, haematuria, haematemesis, or melaena. Her liver and spleen were not palpably enlarged and there were no haemorrhages into her optic fundi. Pulse was normal, and blood pressure 90/70 mm. Hg. Her blood showed a prolonged bleeding-time and a thrombocytopenia without gross anaemia or leucopenia (see Table).

Penicillin was started, but had to be discontinued after one day because of the development of haematomata at the sites of injection. On the day after admission she had a slight haematemesis and melaena, but the purpuric rash began to fade, and in the absence of further evidence of bleeding no treatment was given. The patient was discharged completely well seven days after admission.

Findings in the Blood of Case 1

	At Onset	After Recovery
Haemoglobin (g./100 ml.)	12.0	17.0
R.B.C. (per c.mm.)	4,300,000	5,950,000
W.B.C. (per c.mm.)	5,700	5,700
Platelet count (per c.mm.)	54,000	240,000
Bleeding-time	25 minutes	3 minutes
Clotting-time	10 "	11 "
Prothrombin	100%	—
Capillary fragility	Increased	Normal

At biopsy the bone marrow had a total nucleated count of 44,000 cells per c.mm., but the myeloid and erythroid series showed a normal average differential count. There was no eosinophilia suggestive of an allergic reaction. The megakaryocytes were found to be reduced. They averaged 1 per 10,000 nucleated cells of the bone marrow, as against the normal average of 17 per 10,000, and showed a slight reduction of mature megakaryocytes capable of active platelet production.

Case 2

A merchant seaman aged 26 noticed a sore on his penis when in Indo-China in November, 1948. He was referred to a hospital in Saigon, where *Tr. pallidum* was found in the penile sore. He was then referred to Singapore, where he received a combined course of arsenic and bismuth to a total of 6 g. of neoarsphenamine and 1 g. of bismuth. He returned to this country and first appeared in the venereal diseases out-patient department of the Royal Victoria Hospital in April, 1949. The ulcer had now healed and serological tests for syphilis were entirely negative. He received a course of penicillin consisting of 6,000,000 units in 10 days, after which arsenic and bismuth injections were then recommended. He was given 2.1 g. of "stabilarsan," 2.25 g. of neoarsphenamine, and 1 g. of bismuth.

In July he noticed that he bruised readily, that he had developed a generalized dark rash over his body, that his gums bled readily, and that his urine was dark red in colour. He did not appear to be ill on admission, and was alert, co-operative, and intelligent. He was not anaemic, cyanosed, or jaundiced. There was a general petechial rash on his trunk and limbs, and he was bleeding freely from his gum margins. The urine was a dark reddish colour, and on examination contained albumin and red blood cells. The liver and spleen were not palpably enlarged, and nothing abnormal was found on physical examination of the other bodily systems.

Examination of the blood showed a normochromic anaemia, haemoglobin 9.5 g./100 ml., a leucopenia (3,600 per c.mm.), a slight thrombocytopenia, and a prolonged bleeding-time. Bone-marrow biopsy revealed a marrow hypoplasia.

To relieve the purpura the patient was transfused with 1 pint (570 ml.) of perfectly fresh compatible blood. The next day he was much better and the purpura had almost completely disappeared. Three days later, however, the bleeding from the gums recommenced and fresh purpuric spots appeared on the thighs. A further pint (570 ml.) of fresh blood was transfused. Eight days after admission tonsillitis developed and examination of the blood again showed a normochromic anaemia with a leucopenia (1,900 per c.mm.) and agranulocytosis with thrombocytopenia. One pint (570 ml.) of blood was withdrawn from a case of chronic myeloid leukaemia under treatment in the wards (W.B.C. 112,000 per c.mm.), tested for compatibility, and this was transfused into the patient. This did not produce any significant rise in the neutrophil polymorphs of the peripheral blood. The patient had been on penicillin since the onset. A swab of the tonsillar area gave a pure growth of a streptomycin-sensitive *Bact. coli*, and penicillin was therefore stopped and streptomycin therapy instituted on his ninth day in hospital. Two days later he was clinically very much better; his throat was easier and less inflamed, and the purpura had subsided. On the following day, however, an ecchymosis developed on the left eyelid and spread to involve the whole of the left orbit, and this was followed two days later by a haematemesis, after which the patient became very shocked and cold. Evidence of cerebral involvement quickly followed with severe headache and stiffness and rigidity of the neck. Despite the transfusion of 2 pints (1.14 litres) of fresh blood the patient drifted into coma and died.

Post-mortem Summary.—Aplastic anaemia and purpuric haemorrhages into heart, renal pelves, skin, stomach, and brain, following arsenical therapy. Aplasia of vertebral marrow, confirmed histologically. The immediate cause of death was a massive intracerebral haemorrhage into the cerebellum and occipital lobes of the cerebrum, with sub-arachnoid extension into the posterior fossa. There was associated cerebral oedema and bilateral tentorial herniation, but no evidence of any disease of the cerebral vessels.

Case 3

A man aged 37 first attended the venereal diseases out-patient department of the Royal Victoria Hospital in March, 1947. His wife, who had sero-positive syphilis, was already attending at this time. He himself had no complaints; no history of gonorrhoea or syphilis, and the last extramarital exposure had occurred four years previously. On examination there were no clinical signs suggestive of syphilis, and serological tests for syphilis were negative. His cerebrospinal fluid was found to be normal. Accordingly no treatment was instituted, but he was kept under observation. In March, 1949, serological tests were positive: Kahn ++++, W.R. ++, and Dreyer reading 5.4, and he received a ten-day course of intramuscular injections of penicillin to a total of 6,000,000 units. This was followed by combined courses of arsenic and bismuth injections, and at the end of the second course the serological tests for syphilis were again negative.

When the patient reported for the third injection of his third course in September, 1949, petechial haemorrhages were noted on the skin and he was admitted to hospital. By this time he had received 7.65 g. of neoarsphenamine and 1.8 g. of bismuth. He stated on admission that he had been feeling vaguely unwell for about two months. For about the same time he had also noticed a rash on his face and hands. This had been treated by his own doctor with penicillin cream, gentian violet, and other remedies, without benefit. He complained of some aching in his abdomen and of low back pain. Petechial spots had been noted for a few days before admission and he had had one attack of severe epistaxis. He was an epileptic and had been on phenobarbitone, $\frac{1}{2}$ gr. (32 mg.), night and morning since he was 14. He had received no other drugs, and had suffered from no illnesses apart from an attack of pneumonia in 1937.

Examination showed that he was well nourished, with some pallor of his mucous surfaces. Papular and excoriated eczematous lesions with crusting were present on his beard region, especially on the left side of the chin, with enlargement of the submental lymph nodes. Chronic scaly fissured patches were present on the webs of the thumb and index fingers of both hands, and there were a few patches on the legs. This was considered to be an arsenical dermatitis. Numerous petechiae were scattered over both legs below the knee, with less numerous patches on the back, shoulders, and buccal mucosa. The tongue showed a few petechiae, and there was slight bloody oozing from the gums. The spleen was not palpably enlarged and there were no other bodily abnormalities. Examination of the blood on admission showed: haemoglobin, 10.6 g.%; red cells, 3,230,000; white cells, 2,300 (polymorphs 8%); platelets, 86,000; bleeding-time, 15 minutes; clotting-time, 4 minutes; capillary fragility, positive. Bone-marrow biopsy showed a grossly aplastic marrow with 3% developing myelocytic cells and 2% normoblasts.

A course of dimercaprol (B.A.L.), 1.2 g. in six days, was given. This had little effect on the arsenical dermatitis and none on the marrow aplasia. On the day after admission he was transfused with 1 pint (570 ml.) of fresh compatible whole blood. The next day he complained of a sore throat, and a necrotic ulcer was found on the right tonsil. This was associated with a pyrexia of 101° F. (38.3° C.). A swab from the ulcer showed no microscopical evidence of fusospirochaetes, but on culture gave a profuse growth of penicillin-sensitive haemolytic streptococci. The faecal condition improved and the temperature fell in 24 hours on intramuscular injections of penicillin, 500,000 units daily. On the eighth day another pint (570 ml.) of compatible fresh blood was given, to which he had a pyrexial reaction—temperature 101° F. (38.3° C.)—but without haemoglobinuria. The following day he complained of crampy abdominal pain, with pain and tenderness in the right iliac fossa but no rigidity. This was associated with melaena.

He was maintained with blood transfusions, but on the thirteenth day in hospital he had a haematemesis of about 1 pint (570 ml.). The melaena persisted and blood clots appeared in the faeces. He looked ill and drawn, had abdominal pain, and the abdominal tenderness became more marked. It was considered that he had probably developed an intramural haemorrhage into the intestinal tract. Despite the transfusions his condition deteriorated and he died on the fourteenth day after admission to hospital.

Post-mortem Summary.—Aplastic anaemia following arsphenamine therapy, generalized purpuric haemorrhages into skin, lungs, heart, kidneys, and intestines. Oedema of lungs. The immediate cause of death was massive haemorrhage into the intestinal tract, which was associated with a gross intramural haemorrhage into the hepatic flexure region of the colon, with extension into the perinephric fat of the right kidney. The brain was remarkably free from any evidence of petechial haemorrhages. The bone marrow showed extensive replacement with fat, and only a few basic reticulum cells, plasma cells, and lymphocytes were present.

Case 4

A woman aged 48, with a family of six children, all alive and well, plus one child who died eight years previously, had no history of miscarriages, though her husband had been attending the venereal diseases department since 1939, originally with a sore on the penis and with Kahn ++ and W.R. +++. In January, 1949, she also attended the department with perforation of the hard palate, the only other physical findings on complete examination being the presence of hyperkeratosis of the feet and leucoderma colli. Serological tests were: Kahn ++ and W.R. +++. She received three courses of treatment consisting of 13.65 g. of neoarsphenamine and 3 g. of bismuth. The tests remained strongly positive throughout the therapy.

One month after antisyphilitic therapy was started it was noticed that the patient was somewhat anaemic. Examination

of the peripheral blood revealed haemoglobin 77% (Haldane) and red cell count, 4,200,000, so she was put on ferri sulph. co. (N.F.) 3 gr. thrice daily. The anaemia did not respond to this, and in November, 1949, she was admitted to hospital with severe pallor, nausea, and anorexia, a feeling of tiredness, and breathlessness on exertion.

Examination showed her to be pale, anaemic, well nourished, and without enlargement of the superficial lymph nodes. She was breathless on the slightest exertion, somewhat listless, but co-operative. The tongue was smooth and the abdomen lax. The spleen was enlarged two finger-breadths below the costal margin, but the liver was not palpable. Pulse rate was 90 and B.P. 140/90. The heart showed some enlargement to the right, with a harsh systolic murmur at the apex. On admission the haemoglobin was 21% (Haldane) (3.1 g./100 ml.), red cell count 950,000, white cell count 575, of which 63% were neutrophils. Van den Bergh 1.25 mg. per 100 ml. Bleeding and coagulation times were within normal range. The bone marrow showed aplasia, with marked reduction in the erythropoietic series.

Repeated transfusions of fresh whole blood and a course of dimercaprol were given. She also received injections of 20 µg. of vitamin B₁₂, one ampoule of vitamin K, and 300 mg. of ascorbic acid daily. Six transfusions brought no significant reaction. The seventh transfusion resulted in a marked rigor, so transfusion was stopped. There was no significant improvement in the haematological picture despite the therapy: the white cell count remained low, the haemoglobin ranged between 50% and 29%, and there was constant thrombocytopenia. The patient gradually deteriorated, and died on the 28th day after admission.

Post-mortem Summary.—Aplastic anaemia, haemosiderosis of spleen, slight haemosiderosis of liver, chronic pyelonephritis, and cystitis. The bone marrow showed marked aplastic replacement of both erythroid and myeloid series of cells by fatty tissue.

Discussion

Case 1 is a pure thrombocytopenic reaction to arsphenamine, however this is produced. It showed the characteristic findings peculiar to this type of case—namely, free bleeding from mucous surface, marked fall in circulating platelets, and increased capillary fragility as shown by skin purpura and a positive Hess test. The bone marrow showed no abnormality of the myeloid or erythroid series, and no evidence of the eosinophilia which is usually present in allergic disorders affecting the bone marrow. The megakaryocytes were depressed—few in number, and with maturation arrest—suggesting a direct toxic effect of the drug on the mother cells of the circulating blood platelets. As in most cases of this type, there was a rapid and spontaneous return to normal associated with a rise in the platelet count, which usually begins in 24–48 hours and returns to normal in four to seven days. This good prognosis has been noted in all cases showing this complication of arsenical treatment, and so far no fatalities have been recorded. This differs from the other blood reactions to arsenicals.

Cases 2 and 3 at the onset superficially resembled Case 1, since they developed melaena with bleeding into the skin during the treatment of syphilis with standard courses of bismuth and arsenic by weekly injection. They showed a mild degree of anaemia, with moderate leucopenia, mainly affecting the polymorphonuclear leucocytes, a thrombocytopenia, and prolonged bleeding-time. Despite treatment the haemorrhagic diathesis persisted and the leucopenia progressed to an agranulocytosis with pyrexia and faucial manifestations. This peripheral pancytopenia was associated with a marked aplasia of the bone marrow (panmyelopathy), which affected all elements and was unassociated with any increase in the eosinophil myelocytes, whose increase would have suggested a possible allergic basis for the bone-marrow inhibition. This tendency to massive rather than selective damage of the bone marrow by organic arsenicals has been noted by Plum (1937), who showed that of 47 cases with leucopenia 33 were associated with anaemia or thrombo-

cytopenia. He also pointed out that in arsenical agranulocytosis, in contradistinction to agranulocytosis produced by other heavy metals, there were a relatively high leucocyte count at the onset, a lower age incidence, and a higher incidence in males.

It has been established that heavy metals (including arsenic and gold) exert their toxic effects on a biological system by reacting with the sulphhydryl groups of the protein fraction of cellular enzymes to form mercaptides. The sulphhydryl groups in the dithiol B.A.L. (dimercaprol; 2:3-dimercaptopropanol) compete with the dithiol protein-metal complex in the tissues, thus combining with and eliminating the offending metal. This restores the enzyme system. The therapeutic efficacy of dimercaprol in some of the toxic manifestations of arsenical poisoning has been dramatic. Its effect on arsenical dermatitis has been good (Carlton *et al.*, 1948), and on gold thrombocytopenia and granulocytopenia encouraging (Lockie *et al.*, 1947; Cohen *et al.*, 1947; Ragan and Boots, 1947).

The results of dimercaprol therapy on the haematological disturbances occurring during arsenotherapy are variable. In 12 cases of agranulocytosis following intensive arsenic treatment for syphilis Fisher, Holley, and Fein (1947) reported good results with combined therapy including dimercaprol. Eagle (1946) treated 11 cases of arsenical agranulocytosis with dimercaprol, and 10 recovered; he found, however, that dimercaprol had no beneficial effect on three cases of aplastic anaemia caused by arsenic poisoning.

The first of our cases (Case 2) with agranulocytosis (and aplastic anaemia) did not receive dimercaprol, while the second (Case 3) was given a course of intramuscular injections of dimercaprol in oil to a total of 1.2 g. spread over six days. There was no essential difference in the clinical course of these two cases and no rise in the peripheral cellular counts of the blood, and both ended fatally. The fact that the associated arsenical dermatitis in Case 3 did not respond to dimercaprol suggests that the condition was of long standing (cf. Eagle, 1946). The damage to the bone marrow was severe, as it showed very few developing cells of either the myeloid or the erythroid series, and may have been irreversible.

Case 4 presented as a gross aplastic anaemia from the onset, and purpuric manifestations were not observed, although the platelet count was uniformly low. Despite blood transfusions, oral iron and ascorbic acid, and injections of vitamin B₁₂ and of dimercaprol she showed no clinical or haematological response and her condition proceeded inexorably to a fatal termination.

At the onset the clinical manifestations of a thrombocytopenic purpura of toxic origin are essentially similar to those encountered in the more severe cases of toxic pancytopenia in which all elements of the bone marrow are depressed. Yet the former has a good prognosis and the latter a uniformly poor one. As a case of toxic pancytopenia develops, the initial purpura becomes associated with a gradually increasing anaemia and a leucopenia which proceeds to agranulocytosis. If such severe bone-marrow damage occurs during anti-syphilitic therapy with heavy metals it appears that the prognosis is poor, despite treatment with dimercaprol. All cases of purpura developing during treatment for syphilis should be followed carefully, with repeated blood examinations, to distinguish between the benign and fatal forms which may arise during arsenotherapy.

Summary

Four cases of blood dyscrasia resulting from the toxic effects of organic arsenicals are presented.

One case of toxic thrombocytopenic purpura recovered spontaneously.

The three other cases showed a pancytopenia with marrow aplasia and ended fatally.

The administration of dimercaprol to two of the cases had no apparent effect on the severe toxic manifestations.

My thanks are due to Dr. Hugo Hall for his kindness and co-operation in allowing me access to his cases and clinical records.

CARCINOMA OF THE ADRENAL CORTEX WITH ENDOCRINE MANIFESTATIONS

REPORT OF A CASE

BY

R. J. HARRISON, M.R.C.P.

Consultant Physician, St. James's Hospital, Balham, London

AND

DENIS ABELSON, M.D., M.R.C.P.

Junior Registrar, Postgraduate Medical School of London

Functioning adrenal cortical tumours can produce various clinical pictures. In women, a group of symptoms associated with virilism is referred to as the adrenogenital syndrome. When such abnormalities as obesity, decreased sugar tolerance, hypertension, amenorrhoea, and hirsuties appear without virilism the name Cushing's syndrome is employed. Considerable overlapping occurs, and cases of adrenocortical tumour may show features of both syndromes.

An unusual case is described below in which hirsuties, obesity, and cutaneous striae appeared in a girl before puberty, and in whom menstruation began normally and continued regularly until six months before her death from a metastasizing tumour of the right adrenal cortex. Virilism was absent and carbohydrate metabolism was normal.

Case Report

The patient, a social worker, was one of 12 children. Both parents were short and stout, and one grandmother was said to be exceedingly fat. She herself was plump from infancy, but not excessively so. At 8½ years she weighed 61 lb. (27.7 kg.). At 10 years pubic and axillary hair appeared. She was then sent to the London Hospital on account of obesity—weight 95 lb. (43 kg.), height 4 ft. 3 in. (129.5 cm.)—and was dieted. The following year increasing obesity made further schooling impossible. Striae appeared in the loins, and the pubic hair assumed the male distribution. She complained of occasional migrainous headaches.

A year later, aged 12, she entered hospital with pain in the left loin. Examination showed marked obesity; weight 104 lb. (47.2 kg.), height 4 ft. 4 in. (132 cm.), rubicund facies, pubic hair extending to umbilicus, with fine dark hair over shoulders and arms (Fig. 2a). Blood pressure was 135/95 to 150/80. Investigations showed: blood urea, 21 mg. per 100 ml.; normal intravenous pyelogram and urea-concentration test; cerebrospinal fluid normal; fundi, visual fields, and radiograph of pituitary fossa normal. Radiography showed no cardiac enlargement. In view of the

clinical appearances laparotomy was performed. The adrenals were poorly seen owing to fat, but nothing abnormal was observed except a small lump (? lymph node) on the right kidney: this lump does not appear to have been removed. After discharge she developed left-sided renal colic with haematuria, and subsequently passed a large calculus.

During the ensuing six months she gained 30 lb. (13.6 kg.). Striae were now present not only in the loins but vertically down the abdomen, around the breasts, and on shoulders

FIG. 1.—The patient's Weight Chart.

and thighs. The hirsuties increased, and she developed some coarse dark hairs on the chin and upper lip, and around the nipples and umbilicus. The breasts became moderately large and pendulous, but showed no evidence of functional activity. There were no signs of sexual precocity, and intellectual development was normal for her age, but she was emotionally immature. Blood pressure was 140/90 to 150/95. A blood count showed: red cells, 4,500,000; Hb, 80%; C.I., 0.88; white cells, 11,600 (polymorphs 75%, lymphocytes 15%, monocytes 9.5%, eosinophils 0.5%). Repeated glucose-tolerance tests

showed anomalous values, on one occasion being rather flat and on others normal. At this stage she was presented at the Royal Society of Medicine as a case of obesity and hirsuties of ? adrenal origin (Ellis, 1932). She then received deep x-ray therapy to the pituitary fossa (total pituitary dose 1,120 r). At this time she weighed 180 lb. (81.6 kg.), but rose to 193 lb. (87.5 kg.) two months later, and further x rays were administered (total pituitary dose 420 r). By the time she was 13 she weighed 225 lb. (102 kg.) and her blood pressure was 210/150. Renal-function tests were normal. Four pounds of abdominal fat was now removed at operation by Mr. Perry.

At the age of 15 (Weight Chart, Fig. 1) she weighed 263 lb. (119.3 kg.), her height was 4 ft. 5½ in. (135 cm.), and blood pressure 150/95. She was admitted to hospital for dieting, and lost 36 lb. (16.3 kg.). Following this her blood pressure was 120/70. A glucose-tolerance test was normal. Her photograph at this time (Fig. 2b) shows considerable hirsuties, with generalized obesity. Striae were not well marked, and the face was less moon-shaped than previously.

Her periods began at 16. During the first year she had three periods, each lasting three days, after which they became more frequent and occurred about every 30 days, with occasional intervals of up to two months. The loss at each period was scanty and lasted approximately three days. There was no dysmenorrhoea. She had no interest in the opposite sex.

She lost more weight subsequently, and for the next 14 years, under the dietary supervision of Miss R. Simmonds, she kept below 180 lb. (81.6 kg.). She remained well, active, and at work until three months before her final admission to hospital at the age of 30, when she developed progressive dyspnoea, and a cough with frothy sputum. The headaches became less severe. She began to lose weight (over 2 st.—12.7 kg.—altogether). The sputum became blood-streaked during the month before admission, and for three weeks she had noticed swelling of the ankles and palpitation. Amenorrhoea had been present for six months.

On examination she was afebrile, weight 143 lb. (64.9 kg.), height 4 ft. 6 in. (137 cm.), span 4 ft. 7 in. (139.7 cm.). She was breathless on moving about in bed. There was obesity, especially of buttocks, hips, and abdomen, and the tissues were very lax (Fig. 3). There were widespread pink-and-white striae, generalized hirsuties, and acne of the face and back. The facies was round and plethoric. The hands and feet were small and delicately formed, and the nipples rudimentary, with little underlying breast tissue. Over wrists and forearms were several ecchymoses, some probably spontaneous. The voice was feminine, and the larynx of female shape. External and internal genitalia appeared normal, apart from the male distribution of pubic hair, and in particular there was no gross enlargement of the clitoris. Respiratory system: early clubbing; impaired percussion note at both bases; generalized fine rales. Cardiovascular system: blood pressure 170/120, slight oedema of the legs, but none over the sacrum; jugular venous pressure normal; apex beat impalpable; no cardiac murmurs.

FIG. 2.—(a) Patient aged 12. From Harvey Cushing's *Pituitary Body, Hypothalamus, and Parasympathetic Nervous System*. By courtesy of Charles C. Thomas, Publisher, Springfield, Illinois. (b) Patient aged 15. From Raymond Greene's *The Practice of Endocrinology*. By courtesy of Eyre and Spottiswoode (Publishers) Ltd., London.

FIG. 3.—Patient aged 30 years, a few weeks before death.

Gastro-intestinal system: paramedian and horizontal abdominal scars; there was a large firm mass palpable in the right loin, dull to percussion, moving with respiration, slightly tender, and with a definable upper border. Central nervous system: normal. Urine: albumin, leucocytes, debris, and profuse growth of *Proteus vulgaris*; sugar absent; normal calcium concentration (Sulkowitch's test).

Investigations

Examination of the blood showed: Hb, 101% (14.9 g.); red cells, 5,100,000; marked anisocytosis and polychromasia; moderate poikilocytosis; E.S.R., 8 mm. (Westergren); white cells, 6,000; urea, 19 mg. per 100 ml.; cholesterol, 187 mg. per 100 ml.; chloride, 595 mg. per 100 ml.; sodium, 320 mg. per 100 ml.; potassium, 19 mg. per 100 ml.; calcium, 11.4 mg. per 100 ml.; phosphorus, 3.9 mg. per 100 ml.; alkaline phosphatase, 41.4 King-Armstrong units per 100 ml.; alkali reserve, 47.2 vols. per 100 ml. Total proteins, 7.2 g.% (albumin 3.9 g., globulin 3.3 g., A./G. ratio 1.2); glucose-tolerance test, 81 mg. per 100 ml. (fasting), 122 mg. (half an hour), 150 mg. (one hour), 136 mg. (one and a half hours), 150 mg. (two hours), 100 mg. (three hours); no glycosuria. X-ray examination:—Chest: multiple pulmonary metastases, with mediastinal adenopathy. Skull: normal sella turcica. Dorsolumbar spine: no evidence of secondary deposits. Hands: no osteoporosis. An intravenous pyelogram showed the right kidney to be displaced downward. An electrocardiogram was normal.

Endocrine assays gave the following results. 17-keto-steroids (see Table).

Specimen	Total (Normal 4–22 mg. per 24 hrs.)	β -fraction (Normal up to 10% of Total)	Colour Reaction for Dehydroandrosterone (Allen <i>et al.</i> , 1950)
1	221	34%	Strongly positive
2	256	34%	" "
3 (3 days before death)	150	19%	Positive

Reducing steroids (Dr. C. L. Cope): total neutral reducing steroids were 2.6 mg. a day, using deoxycortone acetate as standard, this being a low normal figure for the method used (Cope and Bain, 1951). Cortisone output, estimated by a biological method (Cope, 1951), was 250 μ g. daily, a high figure.

Clinical Course.—Progressive dyspnoea with cyanosis, terminating in sudden death on December 2, 1950, four weeks after admission.

Post-mortem Examination

Necropsy (Dr. C. V. Harrison) confirmed the clinical diagnosis of adrenal cortical carcinoma with metastases.

Cardiovascular System.—The heart weighed 266 g. The right ventricle was 6 to 7 mm. in thickness, the left 17 mm. The coronary arteries showed a little atheroma. The inferior vena cava was invaded by tumour from the right suprarenal, extending upwards into the right atrium.

Respiratory System.—The right lung weighed 1,135 g. and was largely replaced by innumerable metastases, averaging 2 cm. in diameter. The left lung weighed 532 g. Fine white spots averaging 1 mm. in diameter were scattered throughout, suggesting intravascular tumour. There were also a few metastases up to 1 cm. in diameter in the lower lobe posteriorly. The main left pulmonary artery at the entrance to the lung was occluded by tumour.

The liver, weighing 2,356 g., was directly invaded by tumour in the upper posterior part of the right lobe. Within the liver the mass of tumour measured 13 by 10 by 6 cm., but there were no other deposits, and the rest of the liver appeared normal.

Endocrines.—The thyroid weighed 24 g. and was of normal shape. One small 1-cm. fleshy nodule was present in the middle part of the right lobe posteriorly. The right

adrenal gland weighed 965 g. and measured 18 by 11.5 by 7 cm. It was nodular, had displaced the kidney downwards without involving it, and was adherent to and invading the liver. Most of the tumour was necrotic, but the surviving parts were pale pink and soft. Innumerable vessels were attached to it, and it had invaded the inferior vena cava. The left adrenal weighed 4.5 g., measured 5 by 1.3 by 1 cm., and was normal in position. On section a narrow (1 mm.) line of yellow cortex was visible. The parathyroids (two found) and pancreas appeared normal.

Reticulo-endothelial System.—The spleen weighed 286 g. and showed four metastases in the upper pole, the largest 2 cm. in diameter. Lymph nodes: two large malignant lymph nodes were found in the anterior mediastinum, just above the pericardium. Cervical, axillary, and supraclavicular nodes were normal. Spinal and sternal bone marrow were normal.

Genito-urinary System.—The right kidney weighed 220 g. and showed several recent infarcts. Two metastases, 1.5 and 1 cm. in diameter, were seen. The left kidney weighed 250 g., and also showed fresh infarcts and a 1.5-cm. metastasis near the outer border. Ureters, bladder, and vagina were normal. The uterus was 7.5 cm. long, 4.5 cm. wide, and 2.5 cm. thick at the fundus. The cervical canal constituted most of the uterus, being 4 cm. long. Both ovaries were of normal size, and contained numerous small yellow flecks, but no recognizable corpus luteum. Tubes were normal.

Central Nervous System.—The brain weighed 1,145 g. and appeared to be normal.

Skeleton.—The spine was straight and there was no osteoporosis macroscopically.

Histology

Adrenal Tumour (Fig. 4).—The tumour cells were arranged in solid alveoli and columns separated by fine fibrous strands containing wide vascular channels. The cells varied enormously in size from about 15 μ up to multinucleate syncytial masses. The nuclei were round, hyperchromatic, and vesicular, and the cytoplasm was homogeneous, ground-glass, and eosinophilic. Mitoses

FIG. 4.—Histological section of adrenal tumour, showing trabecular arrangement. H. and E. ($\times 90$).

were uncommon. Vines's androgenic stain was negative. Gomori's alkaline phosphatase stain (Gomori, 1939) was strongly positive in the tumour cells as well as the endothelia of stromal vessels. The Ashbel-Seligman histochemical test (Ashbel and Seligman, 1949), reputedly specific for ketosteroids, was strongly positive. The Sudan IV stain for fat was positive, but this fat was not anisotropic.

The left adrenal was qualitatively normal, and contained rather less lipid than average, but this was anisotropic. Vines's stain was negative. Both lungs showed many metastases in arteries and invading the lung tissue. There was considerable interstitial fibrosis in the left lung, of uncertain origin. Some might have been a reaction to the tumour cells, and some a result of chronic infection. The thyroid

was normal, but appeared to have been a trifle inactive. In the ovary ripening follicles of various ages were present, but no corpus luteum; there were, however, plenty of corpora albicantia and several stomal foci of large, pale, foamy theca lutein cells. The endometrium was thick, and showed a proliferative reaction, but lacked mitoses. Both breasts showed gross atrophy and could be readily mistaken for male breasts. Bone: twelfth dorsal vertebra and first metacarpal were normal. There was no loss of trabeculae.

Pituitary (Dr. A. G. E. Pearse).—Macroscopically the gland appeared smaller than normal. Microscopically, three main changes were present. First, there was a large (3 mm. diameter) chromophobe adenoma containing a few acidophils, ghosts of hyaline basophils, and some mucoprotein secretion. Three smaller chromophobe adenomata were also noted. Secondly, the number of acidophils was considerably reduced, large degranulated forms and small deeply granulated types predominating. Thirdly, over 60% of the basophils were of Crooke's hyaline variety (Fig. 5)—a high proportion by comparison with other reported cases.

FIG. 5.—Histological section of anterior pituitary, showing hyaline changes in the basophils. Trichrome periodic-acid-Schiff stain. ($\times 1,150$)

Discussion

The most striking feature of this case is the length of time during which symptoms suggestive of Cushing's syndrome were present before malignant changes supervened. A search of the literature reveals no comparable case.

The age of onset ($8\frac{1}{2}$ years) also appears to be unusual; most of the reported cases developed symptoms either before the age of 5 years or after puberty.

The diagnostic problem which our patient presented is evident from her history. In view of the absence of clitoral enlargement her case would presumably fall into the category of Cushing's syndrome rather than adrenal virilism (the adrenogenital syndrome). If this is so, the absence of amenorrhoea (except terminally) and of disturbed carbohydrate metabolism is atypical.

Cushing's syndrome has been observed in association with neoplasms and hyperplasia of the adrenal cortex, and with basophil adenomata of the pituitary. In the present case a carcinoma of the adrenal cortex was present, with four chromophobe adenomata of the pituitary; and, considering the long history, it seems highly probable that the initial adrenal lesion at the age of $8\frac{1}{2}$ was either hyperplasia or adenoma. It is difficult to believe that pituitary adenomata can produce Cushing's syndrome except by stimulating the adrenal cortex—and such a belief would certainly complicate our present conception of adrenocortical hormone action. The administration of glucocorticoids produces many of the changes found in this condition (Sprague *et al.*, 1950), and adrenocorticotrophic hormone (A.C.T.H.) will produce such changes only if the adrenals are intact.

Indeed, pituitary basophil adenomata are sometimes found at necropsy in individuals not exhibiting endocrine abnormalities, and are often absent in florid cases of Cushing's syndrome. Admittedly, however, the incidence of such tumours is higher in these patients. The point will doubtless be settled when reliable methods are available for the determination of A.C.T.H. in blood and urine, as a normal blood level would exonerate the pituitary from aetiological responsibility. Such methods are now being developed (Bornstein and Trewella, 1950).

It is possible that in cases of Cushing's syndrome previously reported as being due to basophil adenoma of the pituitary the likelihood of anatomical or functional adrenal hyperplasia was not sufficiently considered; the histological criteria of hyperplasia are notoriously difficult to assess.

It has been thought from time to time that the regular occurrence in Cushing's syndrome of hyaline changes in the pituitary basophil cells (Crooke, 1935) indicated a causal relationship. However, Kepler (1945) was strongly of the opinion that these changes were secondary to adrenal hyperfunction—a view previously expressed by Bauer (1936) and supported by Albright (1942-3). Also, Laqueur (1950) has observed similar histological appearances in the pituitary following cortisone administration in man. This requires confirmation.

Crooke (1946) stated that hyaline cells do not occur in the hypophyses of patients with virilism alone, but Mellgren (1944) did find such cells in four cases of virilism. In no reported case of virilism, however, has the percentage of hyaline basophils exceeded 5, whereas much higher figures are recorded in Cushing's syndrome.

The results of hormone assays in our case conform to the usual 17-ketosteroid excretion pattern found in functioning adrenocortical tumours (Crooke and Callow, 1939)—namely, high total values, high β -fraction, and a strongly positive colour reaction for dehydroisoandrosterone.

The atypical corticoid excretion may possibly be correlated with the atypical clinical picture: it is usual for total reducing steroids to be raised in Cushing's syndrome.

Summary

A case is described in which obesity began in a girl aged 8 years 6 months, and was followed by hirsuties, cutaneous striae, and hypertension. The clitoris did not enlarge, carbohydrate metabolism was normal, and menstruation was unaffected until shortly before death at the age of 30 from a metastasizing carcinoma of the right adrenal cortex. The pathogenesis of Cushing's syndrome is discussed.

Our thanks are due to Dr. Russell Fraser and the staff of the Department of Pathology, Hammersmith Hospital, for their invaluable advice and help in the preparation of this paper. We are also indebted to Dr. A. C. Crooke and Dr. Stuart Mason for details of the early history, to Miss P. M. Burrows for the diagram, and to Mrs. M. E. Connolly of the photographic department.

ISLET-CELL TUMOUR OF THE PANCREAS

BY

D. D. WEBSTER, M.B., B.S., D.P.M.

Senior Registrar, St. Luke's Hospital, Middlesbrough

AND

A. N. BLADES, M.B., B.S.

Pathologist, Central Clinical Laboratory, Middlesbrough

We should like to put on record another case of this disorder, which presented an unusual feature—the co-incidence of hypoglycaemic attacks with the menstrual periods.

Case History

The patient, a single typist aged 20, had no significant previous medical history. In October, 1950, on the first day of the period, after rising in the morning, she had an episode lasting about an hour in which she felt "dazed." Her mother described her behaviour as "trance-like and automatic," and she was slow to respond. She had difficulty in eating breakfast, and was found in the kitchen going through the motions of bread-cutting with empty hands. Nothing else abnormal was noticed, and the trouble cleared during the day.

In November, again at the time of the menses, a similar episode took place, her mother finding it difficult to get her roused and off to work. In December, when the symptoms occurred again, she was taken to her doctor, who found no abnormality and considered that it was either petit mal or a neurosis.

In January, 1951, on the first day of the menses, she had an episode in the late evening in which she flung her arms about in a trance and knocked things over. Her father observed that she perspired freely. By the time the doctor arrived, an hour later, she was normal again. In February a similar "dreamy state" recurred. In between these attacks she lived a normal life, continuing with work and social activities.

In March, on a Saturday at the time when she was due for her period, her mother found that she had not got out of bed after being called. She seemed to be in a "coma-like" state and was unable to do anything for herself. This lasted for a matter of hours, but by early afternoon she improved, her confusion cleared, and she went to bed normally. During the night she was extremely restless and "flung her arms about continuously."

The following day, Sunday, she was "semi-stuporous," but became more lucid towards the evening. During these two days she ate normal meals except for breakfast. That night she was again restless, and the mother reported that occasional "muscular spasms" occurred, when she clenched her hands and stiffened her legs; but her parents managed to feed her with rum and hot milk, which brought about an improvement in her condition, and in the early morning she emerged from the stupor and was perfectly orientated, recognizing her doctor without difficulty and chatting brightly with him.

She remained well all that day, Monday, and in the evening entertained a friend to supper. She went to bed at 10 p.m., but during the night the restlessness recurred with purposeless movements of her arms and legs, and she was not responsive to normal stimuli. Her respirations were rapid and stertorous and her temperature seemed to be raised.

She was admitted to hospital at 2.30 p.m. on Tuesday, March 13. On examination she was in a deep coma, temperature 101° F. (38.3° C.), respirations 30, and pulse 64. Tendon reflexes were increased, abdominals absent,

plantars extensor. An electroencephalogram showed a diffuse disturbance of low frequency and high voltage indicative of a generalized metabolic disorder. Blood-sugar estimation gave 64 mg. per 100 ml.

She was given glucose per rectum and later intravenously, but without response. She died the following night, 33 hours after admission, without recovering consciousness. The blood sugar shortly before death was 20 mg. per 100 ml.

Pathological Findings

At necropsy the pituitary gland was enlarged to one and a half times the normal size, projecting upwards round the stalk, and was golden yellow on section. Histologically the enlargement was in the anterior lobe, in which conspicuous blocks of eosinophil cells were seen. The proportion of these cells was high, but was not significantly beyond normal limits. The thyroid was inactive, with much colloid.

The pancreas contained a rounded dark-red, soft, solid tumour $\frac{1}{2}$ in. (1.25 cm.) across projecting forwards from the gland at the junction of the left and middle thirds. Histologically this consisted of solid islet tissue and was devoid of capsule; it was invading blood vessels, but in view of the remarks of Frantz (1940) it is not possible to maintain that it was malignant, as no metastases were found. The suprarenals, thymus, and ovaries were normal. Apart from oedema of the lungs, no other abnormality was found.

Discussion

Over 400 cases of islet-cell tumour of the pancreas are now on record (Howard, Moss, and Rhoads, 1950). The following particular points are of interest in the present case.

(1) The comparatively short time between clinical onset and death—just under six months.

(2) The occurrence of the symptoms only at the time of onset of menstruation or the day before. Taken together with the enlargement of the pituitary, this suggests that the activity of the tumour is affected in some way by the hormones of the pituitary-ovarian complex. We do not feel competent to speculate on the nature of this interconnection, but a search of the literature shows that at least four other cases are on record in which hypoglycaemic symptoms coincided with the onset of the period (Whipple and Frantz, 1935 (2 cases); Mitchell *et al.*, 1938; Howard, Moss, and Rhoads, 1950). It may be no more than an expression of the alteration of the metabolic rate which occurs at that time, but if this is so it is difficult to see why symptoms are not provoked by exertion or hunger, etc., occurring in the normal course of events at other times. This periodicity can mislead so far as the differential diagnosis from epilepsy is concerned, because, as is well known, this disorder may show itself only at the time of menstruation.

(3) As Duras (1951) points out, the blood-sugar level is no criterion for diagnosis. In this instance the blood sugar on admission was 64 mg. per 100 ml., although the patient was in deep coma. Similar blood-sugar levels, and higher ones, are often found in "prolonged coma" following insulin treatment for schizophrenia, and in these cases it would seem that the prolonged hypoglycaemia causes a cessation of cerebral metabolic processes, since even massive doses of glucose intravenously may produce no effect; it is known, however, that if this glucose is followed by a small dose of insulin the successful termination of "prolonged coma" can sometimes be brought about, and it has therefore been suggested that the second dose of insulin acts as a stimulus to cerebral metabolism. We suggest, therefore, that in the treatment of coma due to pancreatic hypoglycaemia, or of suspected cases, a normal blood sugar should not be allowed to negative the diagnosis, and that after glucose has been given intravenously, without response, a small dose of insulin—for example, 5 to 10 units—might be tried. Rectal

administration of glucose may serve as a first-aid measure, but it is now considered that absorption is very slow and incomplete (Peters and Van Slyke, 1946).

Summary

A fatal case of functioning islet-cell tumour of the pancreas in a woman of 20 is described.

The regular association of symptoms with the start of the menstrual period is noted.

Pathological findings are given, and some suggestions are made about treatment in the light of experience with insulin coma therapy in schizophrenia.

We wish to thank Professor R. A. Willis for his opinion on the pituitary gland and Dr. T. M. Cuthbert, physician superintendent, St. Luke's Hospital, for his advice and opinion on the electroencephalogram.

Medical Memoranda

Intra-partum Uterine Rupture

Uterine rupture, whether in the upper or the lower segment, is one of the most serious catastrophes in obstetric practice, but it is not generally recognized that, of the two, rupture in the lower segment is much the more dangerous.

Dugger (1945) collected 105 cases of uterine rupture (65 died and 40 recovered)—34 were ruptures of upper-segment section scars (27 recovered and 7 died) and 71 were of lower-segment rupture (58 fatal). Watt (1950), in an analysis of 15 cases of uterine rupture occurring in the Toronto General Hospital, found 9 of the lower-segment type with 3 maternal deaths, and 6 in the upper segment with no maternal deaths. Simons (1950) described three cases of lower-segment rupture occurring in women of high parity, and all terminated fatally. Sheehan (1948), in 147 necropsies on patients dying from obstetrical shock, found 20 cases of rupture of the uterus, most of which had been undiagnosed in life. Only one of these was of the upper-segment type, all the others being lateral tears in the lower segment.

Rupture in the lower segment is at the onset extraperitoneal, except in the rare case of posterior rupture. The extraperitoneal rupture which has been given the unfortunate name of incomplete rupture—thereby implying a less serious condition than the transperitoneal rupture—may extend into the plexus of large veins situated in and around the lower segment, or into the uterine veins themselves, without producing any immediate and dramatic change in the patient's condition. The bladder may be involved at the same time. Thus rapid venous bleeding may be taking place and remain undiscovered until the patient suddenly collapses. The earliest clue to the true state of affairs is weakening or cessation of the pains; and recognition of its true significance is absolutely vital, and must not be confused with uterine inertia.

Examination of the patient may now reveal that the presenting part has risen from the pelvis and may be lying in the iliac fossa, and that vaginal bleeding is occurring. Both these signs, however, may be missed at this stage if the significance of the sudden cessation of labour pains is not realized. If the true state of affairs remains unrecognized, then acute circulatory deficiency soon becomes evident, and finally the peritoneum overlying the rapidly developing haematoma ruptures and acute peritoneal shock is

added to acute blood loss. Furthermore, the muscle of the lower segment is unable to contract down upon the bleeding vessels, and blood continues to pour out as long as the heart can maintain a circulation. In this type of case bleeding takes place so rapidly that ordinary transfusion methods cannot supply blood at an adequate rate, and early diagnosis and laparotomy offer the only hope of saving the patient's life.

In contrast, rupture in the upper uterine segment as a rule gives a fairly clear-cut picture of the acute abdomen with intraperitoneal bleeding, but once the uterine contents have been extruded into the peritoneal cavity the uterus can and does act as its own haemostat, contracting down firmly on the bleeding vessels. In this case immediate operation is not an absolute necessity, and time can be taken for resuscitation before operation.

The following cases illustrate the above points.

CASE 1

The patient was a 38-year-old 11-gravida whose expected date of delivery was October 10, 1948. Her previous delivery was by classical caesarean section for severe ante-partum haemorrhage due to placenta praevia. The operation had to be terminated rapidly owing to her poor condition, and she was advised to undergo hysterotomy and sterilization for any subsequent pregnancy, as the quality of the uterine repair was suspect. She had ignored this advice and had not attended any antenatal clinic during the present pregnancy.

At 9 a.m. on October 4 she had sudden severe abdominal pain and was admitted to hospital two hours later. On admission she was extremely collapsed, pale, clammy, and restless, with an almost imperceptible pulse and unrecordable blood pressure. The abdomen showed generalized tenderness and rigidity and the presence of free fluid. A foetal limb could be felt lying superficially under the left costal margin. There was no vaginal bleeding. A diagnosis of ruptured upper-segment scar was made, and morphine $\frac{1}{2}$ gr. (11 mg.) was given intravenously. Plasma transfusion was begun, followed by cross-matched blood. At 5 p.m.—that is, eight hours after rupture—the blood pressure was 76/40, and laparotomy was carried out. Foetus, placenta, and blood were removed, and the uterus was found to be ruptured along the line of the previous incision, and was so firmly contracted that it was almost turned inside out. A subtotal hysterectomy was performed, and at the end of the operation the blood pressure was 92/60. The patient made an uneventful recovery and was discharged on the 12th day.

CASE 2

A 4-gravida aged 35, whose expected date of delivery was April 10, 1950, had her first confinement in Norway in 1946. She was for three days in strong labour; forceps delivery and a pyrexial puerperium followed, and she was in hospital for a month after delivery. The subsequent deliveries were in a nursing-home in this country, the first being a stillborn breech, birth weight 8 lb. 5 oz. (3.8 kg.), after 20 hours in labour, and the second a normal vertex delivery, birth weight 7 lb. 6 oz. (3.2 kg.), after four hours in labour. At the 36th week of the present pregnancy the presentation was a breech, which was easily rotated to a vertex. There was no placental tissue palpable in the lower segment, and the true conjugate measured 4 in. (10 cm.). The inlet was slightly android, but the cavity and outlet were normal. These clinical findings were confirmed by x-ray pelvimetry. The presentation remained a vertex, and she was admitted in labour at full term.

On admission her condition was good, blood pressure being 134/80 and pulse rate 80; pains were occurring regularly every five minutes, and the head was engaged at the brim. After a further two hours in strong labour the presenting part was entering mid-cavity with the cervix two-thirds dilated. At this point the patient had a sensation

of continuous retropubic discomfort, and 20 minutes later the pains ceased completely. I saw her 10 minutes later, when her pulse rate was 86 and blood pressure 126/76. There was no clinical evidence of any deterioration in her general condition. There was marked tenderness on pressure above the pubis, the foetal head could not be felt at the pelvic brim, and rectal examination showed the presenting part to be no longer in the pelvis. There was a moderate bright-red vaginal loss. A diagnosis of rupture of the lower segment was made, and the patient was taken immediately to the theatre, where laparotomy was begun 35 minutes after cessation of the pains, a blood transfusion having been started meanwhile. By the time the operation was begun the blood pressure had fallen to 76/38, the pulse was 126, and the patient was showing evidence of severe blood loss. The peritoneal cavity contained 4 pints (2.2 litres) of blood. There was a ragged tear across the anterior surface of the lower segment extending round the right border of the uterus and down into the cervix on that side. The right uterine vein was completely torn across and was bleeding profusely.

The foetus (weight 9 lb. 3 oz.—4.2 kg.) and placenta lay free in the abdominal cavity, and the body of the uterus was firmly contracted.

Bleeding was controlled, foetus, placenta, and blood were removed, and a subtotal hysterectomy was carried out. At the termination of the operation the blood pressure was 84/40, 2 pints (1.1 litres) of blood having been given. Subsequent progress was uneventful, and the patient was discharged on the 14th day.

Acute Phlegmonous Colitis

As this condition has not, so far as I can find, been described in this country, the following case is of interest. Two cases of acute phlegmonous caecitis were described by Nardell (1949) and a third by Shove (1950). The lesion in the present case lay in the medial wall of the ascending colon adjacent to the ileo-caecal valve. Eleven similar cases were reviewed by Spivack and Busch in 1943.

CASE REPORT

A man aged 22 was sent to hospital by his own doctor in the early hours of January 28, 1949, with a diagnosis of acute appendicitis. Abdominal pain had begun the previous night. During the previous day he had eaten his breakfast and lunch but not his evening meal, and his bowels had been opened once normally. On the night of admission the pain became very acute and he vomited several times. He had been feeling unwell for several weeks, and had been attending his doctor for a boil on his left forearm and an ulcer on his tongue. In March, 1948, he had been in hospital with left lobar pneumonia, and in 1946 he had had a mastoid operation for left-sided acute otitis media. He had been demobilized from the Army in February, 1948, after serving with the Army of Occupation in Germany.

On examination his temperature was 100° F. (37.8° C.), pulse 136, and respirations 32. He appeared pale and shocked. The whole abdomen was acutely tender, with muscle guarding in the right iliac fossa. This prevented any mass from being felt. Rectal examination revealed nothing abnormal. There was a healing boil on the left forearm and a small circular midline ulcer on the dorsum of the tongue near the tip.

An intravenous infusion of glucose 5% and normal saline was begun immediately. An hour later operation was per-

formed under general anaesthesia. When the abdomen relaxed a distinct mass could be felt high up in the right iliac fossa. A gridiron incision was made and only a small amount of serous fluid was found in the peritoneal cavity. The appendix was hanging free from its mesentery and showed no macroscopic abnormality. A solid mass about the size of a golf ball was felt in the ascending colon, and was exteriorized for inspection; it was situated in the medial wall of the ascending colon immediately adjacent to the ileo-caecal valve. The peritoneal surface was pink and grossly oedematous and there were two small areas where the surface was grey and rough. The lesion was well localized, though affecting the ileo-caecal valve and caecum at its periphery. The ileo-caecal valve was not obviously obstructed. The oedema extended into the mesentery, in which several greatly enlarged soft lymph nodes could be felt. The appendix was not removed and the mass was returned to the abdomen. The abdomen was closed without drainage.

The intravenous drip was continued post-operatively, and sulphadimidine, 1 g., and penicillin, 100,000 units, were given by injection four-hourly. The patient's condition, however, rapidly deteriorated: the pulse rate and temperature rose and the blood pressure fell. He died 20 hours after operation.

At necropsy, which was performed by Dr. Richard Pearce, it was noticed that the right thigh was larger than the left. On tapping it with the flat of a knife blade it gave a resonant note compared with the left. Extensive gas gangrene was discovered in the abdominal musculature round the operation wound, in the right ilio-psoas muscle, and in the muscles of the anterior compartment of the right thigh. There was no general peritonitis. The intestinal lesion consisted of an area of acute cellulitis, involving the whole thickness of the intestinal wall, measuring 2 to 3 in. (5-7.5 cm.) across. Except for this area the whole gastro-intestinal tract appeared normal. No trace of ileitis or diverticulitis was found, and there was no obvious ulcer or injury to the mucosa covering the inner aspect of the lesion. The ileo-caecal valve, though involved, was not completely obstructed. There was haemorrhage into the right suprarenal gland and signs of active chronic inflammation in the cells of the left mastoid. Both lungs showed some terminal basal pneumonia and old pleural adhesions. A section of the lesion examined under the microscope showed "spreading anaerobic infection of the whole thickness of the bowel wall." A section of the ulcer of the tongue was reported as "granulomatous ulcer non-specific."

COMMENT

The pathology of this lesion corresponded with that described as the circumscribed type of acute phlegmonous caecitis by Nardell (1949), Bulmer (1947), and Spivack and Busch (1943). It seems likely that the lesion began as a haematogenous focus from the mastoid or the boil on the forearm. The gas-forming organisms then traversed the lesion from the lumen to the adjacent abdominal muscles. In the cases described in the literature there is no record of gas gangrene as a sequel to this lesion. A case of gas gangrene complicating carcinoma of the colon was reported by Wyman (1949), who briefly reviewed other cases of endogenous gas gangrene. Although Spivack and Busch came to the conclusion that removal of the lesion when circumscribed is unjustifiable, it is conceivable that in the present case resection might have prevented the onset of gas gangrene.

Reviews

DISEASES OF THE EYE

Systemic Ophthalmology. Edited by Professor Arnold Sorsby. (Pp. 733; 309 figures and 38 coloured plates. £4 4s.) London: Butterworth and Co. 1951.

This book should have comprehensive appeal to a wide range of readers. "Systemic ophthalmology" is interpreted as covering the innumerable conditions wherein ocular disease is associated with disturbances elsewhere in the body, and, liberally as this is interpreted in the present volume, it embraces much of ophthalmology and also much of medicine. Some indication of its scope is seen in the subjects reviewed. The first section is about the bearing of experimental embryology on ocular problems, the ocular conditions (particularly retrolental fibroplasia) related to premature birth, intrauterine infections (syphilis, rubella, and toxoplasmosis), and the host of genetically determined anomalies which play so obvious a part in ocular pathology. The second part is on inflammations, allergies, and bacterial, rickettsial, viral, mycotic, and other infections which affect the eyes and at the same time have systemic implications; in this section those infections (brucellosis, leprosy, and tropical conditions) which are not particularly common in Britain are extensively discussed. The third part is on nutritional, metabolic (including diabetes and rheumatism), and endocrine disorders; the fourth on central nervous disturbances; the fifth on cardiovascular and haemopoietic conditions; and the sixth comprises a general miscellany which includes the ophthalmic implications of skin diseases, injuries, and intoxications, and such problems as the metastases of tumours, and senile changes.

The book is of composite authorship by a large number of the most prominent among British and American ophthalmologists; the editor must be congratulated on the eminence and distinction of his team. Moreover, the editing has been good in that there are fewer contradictions than are usually seen in work of this type, and little overlapping of the various subjects. As in all such books, the chapters differ in quality, but most of them are good and some excellent—particularly those by Reese and Blondi on retrolental fibroplasia, by Woods on ocular infections, and by Nevin and Kiloh on organic central nervous disturbances. Most chapters show a nice blend of established and new information, giving a fair presentation of the present state of our knowledge and an indication of emergent trends. Finally, the general production of the book is excellent and the abundant figures are often particularly informative.

STEWART DUKE-ELDER.

VITAMINS

Vitamins. A Digest of Current Knowledge. By Leslie J. Harris, Sc.D., D.Sc., Ph.D., F.R.I.C. (Pp. 244; 84 illustrations and 111 structural formulae. 15s.) London: J. and A. Churchill. 1951.

In a small book of some 200 pages Dr. Harris has compiled an excellent digest of current knowledge of the vitamins. The historical approach has been rightly used throughout the book to give the student a balanced insight and understanding of the problems under discussion. A useful list of references is given at the end of each chapter. The book is profusely illustrated with photographs, line drawings, and graphs. Dr. Harris describes concisely and lucidly the clinical, chemical, and pathological effects which result from deficiency of the various vitamins in man and in animals. By the inclusion of an appendix the book is brought right up to date and includes even such recent information as the relationship of vitamin B₁₂ to Castle's intrinsic and extrinsic factors.

The physician interested in nutrition may perhaps feel that too great a proportion of the book has been devoted to pathology and chemistry and more should have been given to clinical aspects of nutrition, including such vexed questions as the existence and recognition of subclinical states of vitamin deficiency in man. In the preface Dr. Harris says that the object of his book is to supply a relatively brief and summarized account of the vitamins which will be useful to science students, medical students, dietitians, and others who wish to gain an impression of the present state of knowledge on this subject. The author can be congratulated on successfully accomplishing this object by producing a small book which is pleasant to read, excellently illustrated, and packed with useful information.

L. S. P. DAVIDSON.

GUIDE TO JUNG'S WORK

The Psychology of C. G. Jung. By Dr. Jolande Jacobi. Fifth edition, new and revised. (Pp. 204; 19 illustrations. 12s. 6d.) London: Routledge and Kegan Paul. 1951.

The writings of Professor Jung, dating from 1902, amount to thirty-five books and almost a hundred contributions to various journals. His work has been that of a pioneer and he has made no effort to systematize his psychological theories and research. The purpose of this book is to provide a synopsis and guide to the essential features in Jung's teaching. This is a wellnigh impossible task, and particularly so because Jung's work is undogmatic in character—the very antithesis of a closed and finished system.

The volume grew out of a lecture, and it still retains something of the lecture atmosphere, particularly in the first two chapters, which occupy two-thirds of the book. A diagram on the blackboard is apt to lose vitality when reproduced in print, and there are too many diagrams here. The third part, on the practical application of Jung's theory, is much more interesting. Here the author gives Jung's views on transference and discusses the dialectical quality of analysis, the therapeutic application of Jung's theory of types, the hypothesis of the collective unconscious and archetypes, the compensatory relationship between the conscious and the unconscious, the process of individuation, and the place in therapy of spontaneous drawing and painting.

The book will be of special interest to those who have read at least some of Jung's books. For the beginner it is too condensed and, alas, too dogmatic, especially in its comments on the psychological aspects of religion. A biographical sketch of Jung provides much interesting material and gives a glimpse of Jung himself. There is also the most complete bibliography of Jung's writings yet published. The translation is somewhat ornate, and there is a tendency to use ungainly neologisms such as influenceability, paradoxicalness, perturbedly. The index is useful and impeccable.

E. A. BENNET.

DICTIONARY OF SCIENTISTS

Chambers's Dictionary of Scientists. By A. V. Howard, B.Sc. (Cols. 500; 70 illustrations. 12s. 6d.) London and Edinburgh: W. and R. Chambers. 1951.

This must have been a difficult book to compile, covering as it does all branches of science from Hippocrates to the present time in a volume of only 250 printed octavo pages. The biographical literature to be consulted is considerable, and there are many dates and particulars still in doubt in spite of the wealth of current historical research. There is evidence in the book that Mr. Howard has read widely and competently assessed the value of conflicting material. His main difficulty, the solution of which makes shrewd demands on the scholarship of the selector, was to decide what to omit. The inclusions, where there are so many obvious possibilities, can readily be determined and justified, but the rejected raise doubts almost beyond solution. We have

for example drawn up a list of some 150 notable biologists who do not appear in the present work. The list includes:

B. S. Albinus, Allman, Martin Barry, P. J. van Beneden, Berengarius Carpensis, Bojanus, Bonnet, Borelli, Camper, Casserius, Charleton, delle Chiaje, Coiter, Cowper, Dalyell, Erasmus Darwin, Delage, Dohrn, Dufour, Dujardin, G. J. Duverney, John Ellis, Estienne (Stephanus), Fernel, Frederick II Emperor of the Romans, Isidore Saint-Hilaire, Goethe, Goodsir, J. S. Haldane, Head, Hernández, Highmore, Kowalevsky, Lacaze-Duthiers, Ledermüller, Leidy, Leuckart, Martin Lister, Looss, Lower, Lyonet, Maupas, J. F. Meckel, Mundinus, Monro Secundus, Walter Needham, Newport, Oken, Oudemans, Pallas, Perrault, Piso, Pliny, Poli, M. G. Retzius, Roesel v. Rosenhof, Romanes, Rudolphi, Ruini, Rumphius, Ruysch, Salviani, the two Sars, Schaeffer, Seba, Severino, Siebold, Straus-Dürckheim, Theophrastus, D'Arcy Thompson, Tyson, Vejdovsky, Vicq-D'Azyr, Vieussens, C. F. Wolff, E. Wotton, and Zittel.

Nevertheless Mr. Howard's dictionary contains 1,300 biographies and 70 portraits, many of the latter having an unfamiliar appearance. There is also a very useful subject index, and a list of Nobel Laureates from 1901 to 1950. Our author may justly claim that his work is concise, authoritative, and even unique, since it is in a way an outline history of scientific discovery and theory distilled from the lives of the men who did the work.

The following corrigenda should be included in subsequent editions of the book: Agricola, b. 1494. Alcmaeon, fl. 510-480 B.C. Anaxagoras, b. probably 500 B.C. Beneden, b. 1846. Belon, b. 1517. Cesalpini, b. 1525. Cushing, d. 1939. Erasistratus, 304-257 B.C. Eustachio, b. 1524. His important *Opuscula* were published during his lifetime in 1563-4. Fabricius, b. 1533. Faber suggested the name *microscope* in 1625. Fontana, 1580-1656. Godlee died at Whitchurch, Oxon. Harvey was not knighted. Herophilus, b. at Chalcedon. Hippocrates died c. 360 B.C. According to Singer there is no evidence that any of the writings forming the Hippocratic Corpus were written by him. W. His, add senior. Jansen should be Janssen. Kircher, b. 1602. Léluse, b. 1526. Libavius, b. 1546. Magendie, b. October 16. Manson was not a bacteriologist but a parasitologist. Mayow, b. December, 1641. "Milne-Edwards" not a hyphenated name—he was of Welsh descent and should be catalogued under Edwards. Fritz Müller, b. 1822. J. Müller's birth certificate gives his name as Johann Peter. He dropped the Peter, and preferred the German-Latin Johannes to Johann. The naturalist who "revealed to the world the new animal kingdom of Infusoria" was Leeuwenhoek and not O. F. Müller. Paré, b. 1510. Ray, b. 1627 (Wray until 1670). Rédi, d. 1696. Steno, d. November 25, 1686. W. Turner, b. 1508. Vallisneri is the correct spelling.

We congratulate Mr. Howard on the completion of his novel and valuable work, which will doubtless pass through many revised and extended editions.

F. J. COLE.

NAIROBI DOCTOR

Under the Sun. (A Memoir of Dr. R. W. Burkitt, of Kenya.) By J. R. Gregory. (Pp. 109. 10s. 6d.) Kenya: The English Press, Ltd.

The doctor's bookshelves are filled for the most part with works of reference. Here is one which, for its entertainment value and the glimpse it gives into a world of exploration and adventure, is well worth the modest price asked for it.

Dr. Gregory recounts the life of his friend and senior colleague, "Kill or Cure Burkitt," the first and for many years the only doctor in private practice in Nairobi, and one of the most colourful characters in the history of the development of British East Africa. He has the Irishman's gift for telling a story, and takes us into history, politics, botany, zoology and ethnology. He tells us of Burkitt's uncompromising views on religion and the treatment of malaria; of his journeys into the wilds when roads were non-existent and motor-cars were open and unreliable; of early experiments with crops; of the old harbour of Mombasa, into which the Arab dhows come crowding in

the north-east monsoon, the white flag of peace flying at their mastheads, and their decks echoing to songs of thanksgiving as their colourful crew furl the large lateen sails; of a zebra hunt by lions and a lion hunt by Masai. *Under the Sun* has the spontaneous charm of a traveller's yarn told by the fireside, and it is at the fireside at bedtime that it should be read.

HENEAGE OGILVIE.

TESTS AND TABLES

Clinical Pathological Data. Compiled by C. J. Dickinson, B.A., B.Sc. With foreword by C. E. Dent, Ph.D., M.D., M.R.C.P., F.R.I.C. (Pp. 32. 4s. 6d.) Oxford: Blackwell Scientific Publications. 1951.

The aim of this slim notebook is to provide in a simple but convenient form tables for the interpretation of clinical pathology data. These are arranged in eight convenient tables. Next, there is a section of practical notes on tests which can be performed without elaborate equipment. This contains some tests which might have been superannuated, such as Haldane's method for haemoglobin estimation, Loewi's test for pancreatitis, and the tests for bile acids and salts in the urine; I cannot believe that these last are of practical value in the investigation of a case of jaundice. Finally there is an index to disease conditions which provides a quick reference to data for the diseases listed in the tables.

The dangers of a book of this kind are easy to see and to overestimate. The advantages are the great saving in time in having information so easily available. An improvement would be to punch a hole in the top left-hand corner so that the book could be hung on the wall in the test-room or consulting-room.

L. J. WITTS.

HISTORY OF NURSING

The Story of the Growth of Nursing as an Art, a Vocation, and a Profession. By Agnes E. Pavey, S.R.N. With foreword by Sir John Weir, K.C.V.O. Third edition. (Pp. 498. £1.) London: Faber and Faber. 1951.

This book tells the story of "the birth and development of each phase of nursing from its earliest beginning to its present form." It is obviously based on wide reading of the literature of the history of medicine and of nursing. The author recognizes that nursing may be an art, a vocation, or a profession, and she has rather artificially divided the subject into three parts concerned with three periods of time. From the dawn of history to the fourth century A.D. is the first period, during which nursing is called an art. This we consider rather unjustified, for there is no evidence that there was any nursing care in prehistoric or early historic times. Garrison gives a more likely account when he states that "the spirit of antiquity towards sickness and misfortune was not one of compassion." The second part is on the period from the beginning of Christianity to A.D. 1850, and during this period nursing is called a vocation. The military and secular nursing orders and the various religious nursing foundations fully justify this title, though the period also covers a time in the seventeenth and eighteenth centuries when nursing was neither an art nor a vocation nor a profession, but merely a lowly and sometimes low occupation. The third part of the book is on nursing as a profession; it starts with an account of Florence Nightingale and brings the subject up to date. In this third part the author gives much useful information, even tracing the effect of the National Health Service on the nursing profession.

The book contains much more than an account of nursing. The reader will find a short history of early medicine in the first 82 pages, and in the second part will learn much about the origin of hospitals. The variety of information provided may have contributed to the popularity it enjoys.

V. ZACHARY COPE.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 9 1952

HEALTH SERVICE CHARGES

The Government's main purpose in deciding to charge patients for drugs and certain appliances obtained through the Health Service is to prevent abuse of it and thereby make it more economical to run. The Chancellor of the Exchequer declared in the House of Commons on January 22¹ that the proposals were designed "to preserve the scope and purpose of the various measures, while correcting or avoiding abuse or faulty emphasis. The real danger to the social services . . . comes from the threat of bankruptcy." Two days later the Minister of Health, winding up the debate, referred² to the rising number of prescriptions in the last three years—from 202m. to 207m., and now to 229m. The total bill for them, he said, is over £50m. a year, and "the consumption of medicine has risen enormously." The same desire to reduce the demand for medicine was no doubt in the minds of the Government elected in 1945, for, when Mr. Attlee, then Prime Minister, announced in 1949 that his Government proposed to introduce charges for prescriptions, he said that the purpose was to reduce excessive and in some cases unnecessary resort to doctors and chemists.³ But he added that the financial saving was not the primary purpose of the charge.

Though the present proposals are open to certain objections, there is little doubt that some patients are importunate in their demands for medicine and cotton-wool, and the figures given by the Minister of Health show that more and more prescriptions are being written. As we pointed out recently,⁴ doctors are ready to educate their patients out of the bottle-of-medicine habit if given half a chance, and a paper by Professor D. M. Dunlop and his colleagues at page 292 indicates that this chance ought to be given. Analysing over 17,000 prescriptions given on Forms E.C.10, they found that 15% of them—the largest single group—were for barbiturates and bromides, and prescriptions for vitamins are surprisingly high in the list for a country where the food, though often dull, is probably adequate and cheap enough to prevent vitamin deficiency if properly chosen and

prepared. Again, some figures given in the *Supplement* at page 50 show remarkably wide variation in prescribing costs between different parts of England. In each of the three last months of 1950 the average cost per person of prescribing was in Chester consistently more than twice what it was in Huntingdonshire. It is difficult to account for discrepancies such as these on purely medical grounds.

While a tax on prescriptions may encourage patients to buy the ordinary household remedies at the chemist's instead of bothering their doctor for aspirins or saline aperients—and in that respect there is much to be said for it—the method proposed to collect this money will have the effect of turning dispensing doctors into tax collectors. The onus is put on the dispensing doctor of obtaining the shilling from his patient, for his remuneration will have a sum of money deducted from it in accordance with his prescribing. Therefore if he fails to extract his shilling—or a larger sum for elastic hosiery—he may be by that much out of pocket.

A wider objection to this scheme is that it is not nearly selective enough. Certain types of patient are exempted from paying the charges—namely, war pensioners being treated for their disability and persons or their dependants receiving grants from the National Assistance Board. Yet it is illogical that a person with a long and serious illness should have to continue paying out shilling after shilling when the declared purpose of the scheme is to prevent abuse of the Health Service. The purpose of the charge seems to have been lost sight of. It is not these patients who plague their doctor for that "ceaseless cascade of medicine which is pouring down British throats," as Mr. Bevan once described it. But the scheme is a blunderbuss that hits them as surely as it does the tonic addicts. Again, it is essential that a scheme of this kind should not constitute a financial barrier between doctor and patient. A shilling, or even a few shillings, is a small sum and to a great many people is not a barrier. But there are certain groups of people to whom it is—in particular old-age pensioners. It is quite wrong that these should be charged under the Health Service or be offered the alternative of undergoing a means test before receiving help from the National Assistance Board.

Sooner or later the Government will have to define its social policy more clearly. The idea behind the National Health Service was surely not that it should be free—for such an idea is in fact absurd—but that it should be available to all without a financial barrier between the sick and their treatment. There is little doubt that few can resist the temptation to get something apparently for nothing—especially out of the

State. The introduction of charges in the Health Service—begun by the Labour Government—will, it may be argued, induce a greater sense of responsibility in those who use it and will lead to its being used more intelligently. Last year the people of this country spent, according to Mr. Gammans, £778m. on tobacco, £488m. on beer, £650m. on gambling, and £107m. on going to the cinema. In the face of this it is difficult to argue that Britons cannot afford token charges for certain medical services. To call such charges financial barriers to treatment is a misuse of language, though there are problems to which thought should be given—old-age pensioners, for example, should be directly exempted from such charges. And doctors should not be employed as collectors. Nevertheless, and economic factors apart, it is surely time to re-examine the implications of a something-for-nothing policy—which to a large extent is the policy of the Welfare State. Some limits must be set to paternal government; a paternalism that saps initiative and responsibility will bring in its train not health but sickness.

CARCINOMA OF THE STOMACH

Carcinoma of the stomach, although strongly challenged by carcinoma of the bronchus, remains the principal cause of death from cancer in this country. In 1940, 13,402 deaths were attributed to cancer of the stomach and duodenum—that is 19% of all the deaths caused by malignant tumours. In 1949 the number of deaths had risen to 14,253, but the proportion had fallen to 18% of all cancer deaths. The increase in the number of deaths can be accounted for by the increase in the number of people alive at ages when cancer is common, and it is not necessary to postulate a real increase in the incidence of the disease. In fact, the death rate from cancer of the stomach and duodenum at ages 55 and above fell during the same period from 1,373 per million to 1,314 per million.

The last decade has seen great advances in the application of gastric surgery: more patients than ever before are being treated by radical resection of their growths, and it is therefore disappointing not to find a greater improvement in the death rate from gastric cancer. However, the proportion of cases in which a radical cure is attempted is still very small, and Jennings¹ has estimated that even under the age of 70 it is likely to be less than 12% of all the patients throughout the country. No other form of treatment has proved to be of general value: no radioactive isotope has been found with a sufficiently great affinity for gastric cancer, and it has not been practicable to treat it by intragastric radiation in the

way that intravesical radiation has been used for growths of the bladder. Some success has been claimed with direct irradiation of the stomach exposed at operation,² but the results have not justified widespread adoption of the technique. Hopes of reducing the mortality have been centred on earlier diagnosis, more general use of resection, and more extensive removal of the growth by total gastrectomy.

Not all surgeons are agreed about the value of partial gastrectomy. As a palliative operation it relieves distress and eases the patient's last months, but the extent to which life is lengthened is uncertain. The five-year survival rate among patients who recover from the operation of resection for carcinoma varies in different clinics between 22%³ and 35%,⁴ but the proportion of all patients admitted to hospital for gastric cancer who survive five years is only between 3%⁵ and 7%.⁶ The difference is due to the great number of cases which are not considered operable when first diagnosed in hospital. The question therefore arises whether the improved outlook in the operated group is to be attributed to the operation or whether it is due to the selection for operation of that group of cases which is, in any event, likely to live longest.

The answer could most clearly be provided by a clinical trial in which a number of patients suitable for resection were treated palliatively and were compared with a similar group in which the growths were resected. It is doubtful whether in the present state of knowledge any surgeon would be prepared to undertake such an investigation, and it becomes necessary to try to assess the results of surgical treatment by comparisons between series treated at different places or at different times. The comparison between groups of patients treated at different hospitals is full of pitfalls because of the differences that occur in the types of patient presenting themselves for treatment—differences, for example, in age and in suitability for operation. In these circumstances the detailed follow-up of 375 patients with carcinoma of the stomach reported by Drs. B. F. Swynnerton and S. C. Truelove in this issue is of interest. Their results gain in importance because of the completeness of the follow-up—information was obtained about every patient—and because the Radcliffe Infirmary, at which the patients were treated, “functions as a community hospital and its patients are representative of the major illnesses in the area.” It may therefore be

hoped that the type of case attending the hospital will be similar at different periods and that any improvement achieved in the final results can be attributed to earlier diagnosis or improvement in the method of treatment.

Swynnerton and Truelove's figures are in close agreement with other series reported: 5.6% of all patients followed for five years remained alive; of those subjected to radical resection the proportion was 23.3% and of the remainder it was 0.7%. The outstanding observation, however, is that among the patients treated by radical resection the survival rate was greater when the pre-operative history was long and less when the pre-operative history was short. With a history of under six months the three-year survival rate was 8%, with a history of six months to two years it was 36%, and with a history of over two years it was 54%. These results could not be explained by any association between a short history and the age of the patient or the site of the growth, nor by there being a preponderance of "so-called ulcer-cancers" in the group with a good prognosis. Swynnerton and Truelove concluded that the patients who gave long histories must have had slowly growing cancers, and that this was the explanation of their longer survival.

It is not the first time that an association has been recorded between a long history and a good prognosis in cancer of the stomach. It has also been noted for cancer of a number of other sites: in fact, in the first report issued by the General Register Office of the results obtained by the national system of cancer registration, Stocks⁶ found that "the only kinds of cancer . . . which show a definite advantage to those with short intervals since earliest symptoms are epithelioma of the skin and cancers of the breast and prostate." For cancer of the stomach, the proportion of patients alive at the end of one year was greatest in those with histories of 18 to 24 months, and was greater in those with histories of over two years than in those with histories of under one year. The importance of such findings has been discussed in detail, by Park and Lees,⁷ who refer particularly to cancer of the breast. They conclude that the apparent curability of cancer of the breast by operation can be explained entirely in terms of the variation of the growth rate of the tumours; that it has not been proved that the survival rate of cancer of the breast, as measured by the proportion surviving five years, is at all affected by treatment; and that, if treatment is at all effective, the effectiveness cannot be greater than that required to increase the overall survival rate by more than 5 to 10%. It is doubtful whether the nature of the material analysed by Park and Lees

is adequate to justify their detailed calculations, but they have made a strong case for attributing much of the benefit customarily allowed to surgery to the selection of patients with a naturally good prognosis.

In the absence of a controlled trial, investigations such as Swynnerton and Truelove's offer the best hope of assessing the true value of radical resection. If it can be assumed that the types of patients coming for treatment to a district hospital are comparable over a number of years, an improvement in the five-year survival rate with an increase in the proportion of cases treated by resection can be taken to indicate a real advantage for surgery. Patients over 70 provide a particularly suitable field for study. Before 1944 radical resection was not attempted at the Radcliffe Infirmary in any patients over 70; since then it has been carried out in 22% of such patients. The total numbers are small, but if they could be combined with figures for two or three other hospitals it might be possible to determine on a firmer basis and without great delay the value of resection in gastric cancer. Meanwhile, if patients are to face the operative risks attendant on total gastrectomy, it is to be hoped that a controlled trial will be undertaken to demonstrate the advantages of this operation over partial gastrectomy.

A GREAT THINKER

When Jung's name is mentioned it recalls the triad of pioneers in psychiatry—Freud, Jung, and Adler. Certainly there were links between these three in days gone by. But the developed work of Jung is unique and has little in common with Freud's psycho-analysis or Adler's individual psychology.

Professor Jung, who will be 77 next July, has retired from active practice, but he is still a prodigious worker and writer. He was born in Switzerland, the son of a Swiss pastor, and he has always lived and worked there. His contributions to psychology, to psychiatry, and to related subjects make a library in themselves. The importance and originality of his mind are attested by the fact that he holds honorary degrees from eight universities, including Oxford and Harvard. He is also an Honorary Fellow of the Royal Society of Medicine.

Jung took his medical degree at Zurich University, and after qualification he worked for eight years in close collaboration with his distinguished chief, Eugen Bleuler. On looking back we can see how much Bleuler and his enthusiastic staff did to replace the old descriptive work of Kraepelin by a new interpretative psychiatry. Jung himself in these years was carrying out intensive psychological and physiological

studies upon the patients, in order, as he put it, to detect the intruders of the mind. In 1906 he published his *Psychology of Dementia Praecox*, the fruit of three years' experimental investigation and clinical observation. From then on Jung's position as a pioneer was established.

The hypothesis of mental life outside consciousness—the unconscious—was of course well known before his time. But its nature and aim (if any) was a mystery. Jung examined the hypothesis of the unconscious critically, and he proved, by methods which others could repeat, that the unconscious was a reality and that it acted autonomously. The term *complex* was coined by him to describe the concentration of mental energy, within the unconscious, around certain ideas. The complex was not a theory but an observable fact, and its effect could be demonstrated objectively. But he was still unable to explain the psychological mechanism which brought the complex into being. When we are in the grip of a complex the limitations of "will-power" soon become evident. It is exactly as though another person interfered and prevented us from carrying out our conscious intentions. He quickly realized that Freud's views on repression threw a new light upon the origin and meaning of this. Working independently they had reached complementary conclusions concerning the unconscious. Bleuler and Jung were the first orthodox psychiatrists to give public backing to Freud at a time when his highly controversial views were subject to intense criticism.

But, while freely admitting the importance of Freud's work, Jung retained an independence of judgment. He was unable, for example, to ascribe to the infantile sexual trauma the exclusive importance seemingly attributed to it by Freud. Jung felt then—as indeed he feels to-day—that psychology was too young a science to formulate dogmas, and he declined to give "an unconditional surrender" to the dogma of the infantile sexual trauma. The publication of Jung's *Psychology of the Unconscious* showed clearly that his views had diverged considerably from Freud's, and thereafter the two worked apart.

The terms *extravert* and *introvert*, current in every branch of psychology—not to mention everyday conversation—were introduced by Jung. As a physician he was forced to take account of the peculiarities of individuals, and he noted that in some people interest, mental energy, flowed naturally outwards. The object, the outer world, claimed attention. Interest was projected, or perhaps injected, into life. For others interest lay in the inner, subjective sphere. The former he designated *extraverts* and the latter

introverts. This typology expressed only the relative predominance of one or other mechanism, for everyone expresses both mechanisms in his life rhythm. This grouping of personalities into two general attitude types, showing the prevailing direction of mental energy, was later supplemented by what Jung called the basic psychological functions (thinking, feeling, sensation, and intuition), and each of these appears in *extraverted* or *introverted* form. By this typology psychic data could be classified, and this opened the way for a comprehensive study of the psyche itself and the formulation of theories about its structure. Facts first and theories later is the keynote of Jung's work. He is an empiricist first and last.

Typology has had a considerable vogue, and we have had classifications in terms of physique, physiology, and a mixture of physical and psychological traits. Jung's typology is different: his attention is focused upon the mind itself. He makes no claim that his typology is perfect or even complete. But he values his type theory because, like a compass, it enabled him to orientate himself in the intricacies of human psychology.

Jung's most significant work has been in the study of the unconscious. He recognizes two divisions in this realm: the personal unconscious—a superficial layer derived from repressed or forgotten conscious material—and a non-personal or collective layer not derived from personal experience, but inborn. The former was first described by Freud—a great achievement. But Jung, from his observation of clinical facts and his knowledge of human history, came to see that psychology was more than a personal discipline. His analysis of abnormal people (and so-called normal people too) constantly revealed material which he could not account for in terms of the life history of the patient. This material, he felt, could be comprehended only by postulating a collective background from which the individual consciousness arises.

The collective unconscious is, in brief, a non-personal functional system manifested in pre-existing forms or archetypes which do not develop individually but are permanent attributes of mankind. None of Jung's empirical concepts has met with so much misunderstanding as this hypothesis. Are there or are there not such universal forms? If they exist—and Jung has advanced considerable evidence to show that they do—then there is a region of the psyche which one can call the collective psyche, and psychological explanation must take notice of it. As Jung points out, even the most individualistic psychology accepts the hypothesis of instincts, which, as all agree, are by no means personal peculiarities, but specifically formed motive forces which act in

their inherent directions despite any degree of enlightenment. There is reason, therefore, for assuming that the archetypes of the collective unconscious are the images of the instincts themselves.

Many have found Jung's concept of the collective unconscious difficult to understand, and some have even reproached him with being a mystic. Yet our minds, like our bodies, have their history, and each gives evidence of a long ancestry. Research into the unconscious reveals discoveries analogous to those made in studying comparative anatomy. There is nothing mystical or obscurantist in this. When we examine the basic structure of the mind, as Jung has done, we find these collective, pre-existent, supra-personal forms. We do not, however, find the evidence for them without some hard work.

Therapy in Jung's system of analytical psychology is largely influenced by his views upon mental structure. The outlook is prospective rather than retrospective, for the concept of an autonomous psyche brings with it teleological implications. The attempt to explain neuroses and other disabilities in terms of long past events is of much less importance than the significance of the present problems and the future possibilities of the individual. Hence his emphasis upon dreams—which show the direction in which the unconscious is moving—and upon painting and drawing, which give an outlet for the creative power of the mind. The effect of these often crude pictures upon patients is widely known, and art therapy is now practised in practically every mental hospital. The aim of therapy, Jung says, is to bring about a state of mind in which the patient begins to experiment with his own nature—a state of fluidity, change, and growth.

Those without experience of such things as dream interpretation and painting therapy may naturally prefer more familiar weapons. Jung would share their prejudice. But he has evolved his methods out of the necessities of therapeutic work and has proved their worth. He makes no claim, however, that his is the only right way but retains the open and inquiring mind. His modesty is indeed disarming.

Jung's greatness nevertheless does not lie in devising therapeutic tools but in the light he has thrown upon the hinterland of the human mind. Toynbee, in recounting his efforts to understand the ebb and flow of civilizations, found inadequate the many would-be scientific explanations, and adds, "If I had been acquainted at the time with the works of C. G. Jung they would have given me the clue." Those who have read the work of Jung with an unbiased mind will agree that man's understanding of man has been vastly enriched by the genius of this great thinker.

SLEEPING POSTURE IN PHTHISIS

A number of diseases in the lung—including lung abscess, bronchiectasis, and pulmonary tuberculosis—can be caused or spread by bronchial aspiration of infective material. Helm¹ has shown that spread of tuberculosis may occur during sleep, and that the distribution of the disease in the lungs may depend on the patient's posture. Spread of tuberculous disease to parts of the lungs not previously affected is common after severe haemoptysis, or in patients with a bronchopleural fistula. It also occurs quite often in patients whose bronchial trees are not so obviously flooded with infected material. Two patterns of distribution are especially common: in patients with cavities in the left apex the disease spreads to the axillary sub-segments of the right upper lobe, and in those with cavities at the right apex to the corresponding part of the left upper lobe and also to the lingula. If postero-anterior radiographs only are taken, a wedge-shaped lesion in the middle zone will be seen, with its apex towards the hilum.

The distribution of any fluid which enters the trachea or bronchial tree is determined by gravity, provided it does not excite a cough reflex. When the patient is lying on his back it will run into the bronchi to the apical segments of the lower lobes, for those will be the most dependent. Brock² has stressed the importance of posture in the aetiology of post-operative lung abscess, which most commonly occurs in this segment: during anaesthesia septic material may be aspirated, and if the patient is supine the bronchus to this segment is the one it is most likely to enter. If the patient lies on his right side fluid will run along the lateral wall of the trachea and right main bronchus and then into the upper-lobe bronchus; it will enter the anterior and posterior segmental divisions about equally, and flow particularly to their most dependent parts, the axillary sub-segments. It is unlikely to enter the middle-lobe bronchus, because its origin lies anteriorly. If the patient lies on his left side the fluid similarly enters the upper-lobe bronchus and reaches the axillary part; it also runs into the lingula, since its bronchus is a branch from the inferior wall of the upper-lobe bronchus. Such a distribution, expected on anatomical grounds, can be demonstrated with radio-opaque oil, as was shown by Wu and T'Ang.³ During sleep the cough reflex is depressed, and tuberculous sputum could be aspirated into dependent lung in the same way.

Helm reviewed 1,200 tuberculous patients. Among them were 157 with unilateral cavernous disease and contralateral bronchogenic spread, and 93 with unilateral cavernous disease and a normal opposite lung. He studied the posture in which these patients slept. Many of those with spread to the opposite lung slept constantly on the side to which spread occurred; but most of those without spread slept on the side of their cavity. The figures were statistically significant and give strong support to the theory that bronchial aspiration during sleep is an important factor in the spread of tuberculosis

¹ *Thorax*, 1951, 6, 417.

² *The Anatomy of the Bronchial Tree*, 1946, London.

³ *Amer. J. Roentgenol.*, 1937, 37, 180.

from a cavity. As a corollary, Helm recommends that all patients with unilateral disease should be instructed to sleep on the side of their lesion.

EPIDEMIOLOGY OF SCARLET FEVER

For well over half a century mortality from scarlet fever has been falling. The great quickening of this trend after the introduction of sulphonamides is evidence of the effect of improved methods of treatment, but there can be no doubt that there has been for a long time a steady decline in the severity of the disease. Wide fluctuations in its severity—sometimes it has been regarded as a very grave illness and at other times as trivial—have been characteristic of scarlet fever since the days of Sydenham, but modern therapy should help to offset any future tendency of the disease to lose its present mildness. The decline in mortality has not been accompanied by reduced prevalence, and there is evidence that the disease is as common as ever. This failure to control the prevalence of scarlet fever is not surprising if Okell's¹ conception of its epidemiology is accepted. His view was that scarlet fever appears merely in a small proportion of those infected with haemolytic streptococci, the victims lacking antitoxic immunity to erythrogenic strains. Scarlet fever cannot be controlled by measures that are not also directed to the control of non-scarlatinal streptococcal infections. When sharp outbreaks occur, or when the infection is spreading in a school or similar community, bacteriological investigations will give essential help to those attempting to control the spread, but it would be impracticable to apply such investigations as a control measure in the general community.

The report² by the World Health Organization on the trend of scarlet fever during recent years provides figures of incidence throughout the world since the end of the war. In a large part of the African and Asiatic continents the disease has been relatively insignificant. In general the same has been true of the American continent with the exception of Canada and the United States. Incidence in Europe during this period, however, greatly exceeded that in Canada and the United States, and an interesting comparison is made between the post-war trends in North America and Europe. In the United States between 1946 and 1950 the annual number of cases fell from 116,000 to 57,000, whereas in the European continent notifications rose from 239,000 to 520,000. The trend during this period, therefore, has been in opposite directions on the two sides of the Atlantic. The attack rate also has shown wide differences, for in 1950 the rate in the U.S.A. of 37.7 per 100,000 was less than one-tenth of that experienced in Berlin and Finland. The attack rate in the United States has been well below 100 per 100,000 for the whole of the post-war period, though before the war it kept steadily above this level. Whether the reduction means that the community is developing resistance to the numerous strains of haemolytic streptococci remains to be seen.

FAMILY RESEARCH AT PECKHAM

Two years ago the Pioneer Health Centre at Peckham had to close its doors through lack of funds, and last May the land, buildings, and equipment were sold to the London County Council for £60,000. At a meeting of the L.C.C. on February 5 the health committee presented a report containing proposals for the establishment of a medico-sociological research unit at the Peckham centre (now known as the Queen's Road Health Centre, Camberwell). The general aim of this research unit will be the study of the conditions required for the healthy development of the family and the extent to which medical and associated social services provide these conditions. Among the problems which it is hoped to investigate is that of morbidity—its definition, the methods of assessing it (including minor deviations from health), and the estimation of the nature and amount of morbidity in the community. Upon this will follow a study, with particular reference to general practice and the medico-social services, of the means by which and the extent to which illness is treated. It is proposed to establish at the centre a family club. The members of the club, together with persons attending the clinics and other activities at the centre, will, if they are willing, form the raw material for the research workers. It is hoped also that with the co-operation of local general practitioners some of their patients will take part in the investigations. No one, of course, will be included in the research without his or her consent.

The research programme requires the engagement of a director with a small staff, and the appointment of a governing body to deal with administrative matters. It is suggested that the governing body might include two members of the county council, its medical officer of health and education officer, two representatives of the local medical committee (at least one of whom shall be a local practitioner), a representative of the London School of Hygiene and Tropical Medicine, and of other postgraduate or undergraduate schools. The director would be a qualified medical practitioner of maturity and outstanding ability, for whom an appropriate salary would be about £2,500 a year, and under him would be research assistants. The London County Council has no powers under the National Health Service Acts to carry out research of the type proposed, but it is hoped that funds will be made available, say for five years, from one of the trusts or foundations interested in medico-sociological research, or from the Medical Research Council. By establishing a family research unit on these lines the L.C.C. will help to keep in being what has been described as "the only experimental station where mankind can pursue one aspect of his proper study—man in his environment."¹

The next session of the General Medical Council will begin on Tuesday, February 26, at 11 a.m., when the President, Professor David Campbell, will take the chair.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

COMMON CAUSES OF CURABLE BLINDNESS

BY

JOHN FOSTER, M.B., F.R.C.S., D.O.M.S.

Ophthalmic Surgeon to the General Infirmary at Leeds

On peut dire sans paradoxe que selon toute vraisemblance si les hommes étaient condamnés à vivre cent cinquante ans, ils seraient tous aveugles.—P. BAILLIART, 1950.

Bailliant's statement is a reminder that some half of those blind enough to require subsidy or support in a modern industrial community are not, and never have been, susceptible to treatment. Even those who are treatable respond during a limited period only, so that for the sake of the community, as well as for the sake of the individual, diagnosis should be made early and treatment should be adequate. Space limits this article to a consideration of the commonest treatable causes of blindness in Great Britain—namely, trauma, iritis, acquired glaucoma, cataract, and myopia.

Trauma

Blindness from trauma is as spectacular as it is unnecessary, and, though the actual incidence of binocular traumatic blindness in England is relatively low, it provides an important field for prophylactic ophthalmology. Industrial blindness is largely monocular, patients losing the sight of one eye being 10 times as numerous as those who lose the sight of both. But only half the cases of traumatic blindness are industrial. Children are particularly prone to trauma, and, although many penetrating wounds are from unlikely and unforeseeable causes, in at least two fields precautions are possible. For instance, any child who sets off a firework by himself should wear "anti-gas" or similar goggles. Accidents from air-guns are also preventable; at least seven times in the past two years I have wished that air-guns could be sold with a large red "L" on the butt, to be planned off only when a boy is certified by a responsible person as understanding the ordinary routine of handling a gun. Motor accidents, too, play their part in causing traumatic blindness, usually by producing optic atrophy from basal fracture. A crash helmet might be "required wear" for motor-cyclists in this country; in Belgium they seem to have become *de rigueur* as a matter of fashion.

In the industrial field the value of goggles remains relatively unrecognized. It is true that goggles are not always comfortable to wear, but there is no doubt that where their use can be enforced by precept or example the incidence of industrial eye injuries drops to practically nothing. In industry 63% of eye injuries are due to abrasive particles; these require careful removal, as they tend to combine chemically with the surface of the cornea, just as they do with the back of a pair of glasses. If the particle is carefully removed, with the surrounding "rust ring," with a cataract needle under cocaine and in good illumination, most of these injuries heal fairly rapidly, although it is advisable to insert a mydriatic and to keep a daily watch until the eye is healed. If the injury is slight, homatropine 2% should be used for mydriasis rather than atropine, as the latter leaves vision blurred for 10 days. If infiltration occurs round the abrasion the case is best referred to a specialist, as this may foretell a hypopyon.

Six out of every 1,000 miners employed have eye injuries annually, mostly small corneal ulcers due to a foreign body which becomes loose and disappears by the time the

eyes are examined. The use of 30% sulphacetamide drops in all cases of eye injury in pits has in some areas halved the average time lost from work.

Injuries from chisel particles comprise some 13% of all injuries and are very much more serious than those due to abrasives. A particle which flies off and is sharp-edged may penetrate into the interior of or right through the eye. If a patient states that he was striking a metallic object or a stone with a hammer or a chisel and that a fragment struck his eye, unless that fragment is visible on the surface, he should be sent to hospital to be radiographed. The entry wound of many such particles is invisible except on careful ophthalmic examination. Such particles are of magnetic steel, and, with the aid of an electro-magnet, can as a rule be removed. Unfortunately, however, the damage done to the lens often leads to a cataract, and though this can be removed in young people by linear extraction the eye will not focus until corrected by a strong lens. The wearing of such a lens produces diplopia in most people. A contact lens (where tolerated) may allow binocular vision, but the introduction of a small plastic lens between the lens capsule and iris, a technique described last year by Harold Ridley, may, if tolerated indefinitely, open up new possibilities. The longest period recorded so far is two years, and the technique has until now been used by only a few surgeons. In many cases fibrous tissue formed as a sequel to the transit of the particle through the vitreous leads to an untreatable retinal detachment.

Corneal burns are not uncommon from molten metal, acids, or alkalis. Molten metal should be removed so far as possible at the first-aid station, but no attempt should be made to neutralize acids or alkalis chemically. The best immediate treatment is to put the face under a running tap or in a basin or bucket of water with both eyes open in an attempt to wash out as much of the chemical as possible. Of all corneal opacities the chemical burn responds worst to corneal grafting.

Iritis

The differential diagnosis of iritis from glaucoma is a classical ophthalmic problem, and, while some cases are clear-cut, others may present difficulties to the most expert. An inflamed eye with a clear cornea, unstained by fluorescein, and a muddy iris indicates iritis. If the cornea shows a generalized haze the probabilities are in favour of interstitial keratitis in a young person, and of primary or iritic glaucoma in the middle-aged. The pupil is the most reliable guide in these cases, in glaucoma being semi-dilated and vertically oval, and in iritis (unless atropine has been used) smaller than that in the normal eye and irregular in shape (Fig. 1). The presence of posterior keratic precipitates is not always a reliable distinction, for though they are always present in iritis they can also occur to a

FIG. 1.—(a) Glaucoma pupil: semi-dilated and oval, cornea hazy. (b) Normal pupil. (c) Iritis pupil: contracted and crenated.

lesser extent in primary glaucoma. In cases of doubt the patient should be sent to an expert, but if this is not possible he should be treated temporarily for glaucoma.

Obvious iritis, even if accompanied by secondary glaucoma, should be treated initially as iritis. Here the chief difficulty is to find the cause. The happy certainty of our grandfathers that iritis was largely syphilitic and could be cured by inunctions, of our fathers that it arose from septic foci and could be treated by extraction of teeth or drainage of sinuses, or of our Continental colleagues that it is tuberculous and should be treated by tuberculin, has been replaced by a degree of therapeutic nihilism. Tests should be carried out to exclude these possible causes, but in most cases they will be found to be negative. A certain number of cases have been attributed to sarcoidosis, and these benefit from the controlled administration of calciferol by mouth.

In general, the treatment of iritis consists in covering the eye, applying heat by spoon bathing (for 10 minutes three times a day) or short-wave diathermy, and giving 1% atropine sulphate eye ointment once or oftener a day to keep the pupil dilated. When synechiae are marked the injection of "mydracain" (a mixture of atropine, cocaine, and adrenaline) subconjunctivally may be effective. Cortisone drops (5 mg. per ml.) four-hourly are the most recent effective measure. A similar effect is probably obtained indirectly by the more severe measure of pyretotherapy (intravenous injection of 1 ml. of T.A.B. vaccine diluted to 25 million organisms per ml., to be followed in 72 hours by a further 2 ml.).

Where possible the use of atropine and rest of the eyes should be continued for two to three weeks after the eye has become "white," though dark glasses may replace the eyepad. If after the attack has subsided the pupil is completely bound down, the iris bulging forward, or the tension raised, iridectomy is indicated.

Congestive (Narrow-angle) Glaucoma

In all cases of migraine or neuralgia the eyes must be examined, as traditionally acute glaucoma is associated with acute supra-orbital pain and vomiting. These symptoms are not always present, however, and the main diagnostic feature in a patient over 40 is a history of rainbow rings round lights and blurred vision when tired. The acute attack is usually, though not invariably, a more severe version of previous minor attacks. It should not be forgotten that the "halo" appears colourless to some patients. The cornea is usually small, hazy, and surrounded by ciliary injection; the anterior chamber is shallow. The pupil is semi-dilated and oval: this is the most important diagnostic feature. Traditionally the eye feels harder than normal, but as the "tactus eruditus," if it exists, is probably possessed by few people, it is better to rely on visual rather than tactile signs. Berens, of New York, has recently produced a cheap plastic tonometer for the general practitioner's use, but this is not yet available in Great Britain.

If pain is a feature of the case, morphine $\frac{1}{4}$ gr. (16 mg.) should be given, and 0.5% eserine drops in oil inserted half-hourly in the eye. If in two to three hours the pupil is not contracted and the cornea is still hazy, the patient should be sent to an ophthalmologist, as iridectomy will probably be necessary. This difficult operation has been greatly simplified by what is known as the *ab externo* technique, in which a cut with a knife of the Gillette D type is gradually made through the sclera behind the limbus until the iris prolapses. A large iridectomy is then performed. The prognosis of this operation is good, 90% of the cases being cured.

In some cases a severe crisis never occurs. The patient has a series of minor attacks with haloes and dimness of vision which produce a gradual cupping of the optic nerve and diminution of the visual field as in chronic non-congestive glaucoma. The cornea is clear and smaller than normal, the pupil reaction to light is sluggish, and the tension is

raised during the attacks, though it may be normal between them. Pilocarpine 0.5% drops may control the attacks as indicated by the disappearance of the halo, but if attacks recur at intervals of a month or two the tension is best measured by tonometer and operation should be considered. In these more chronic cases the effect of basal iridectomy can be reinforced by cutting away the anterior lip of the scleral incision with punch forceps (irido-corneo-sclerectomy). The prognosis is not so good as in the acute type.

Non-congestive (Wide-angle) Glaucoma

This condition is difficult both to diagnose and to treat. Externally the eye may look normal; the anterior chamber may be deep and its angle wide, though the pupil reaction may be sluggish to light. The patient complains of little except difficulty in reading, and the presbyopic patient who requires his reading-glasses changed more than once every two years should always be suspected of this condition; his optic disks should be examined to see if they are pale or "cupped." The clearest indication of "cupping" is that the vessels appear to stop short at the edge instead of running to the centre of the disk and are crowded to the nasal side. If there is any doubt, a careful examination of the visual field by an ophthalmologist and tonometry in the early morning after imbibition of fluid are required.

Once the diagnosis is made 1% pilocarpine drops are instilled once or oftener a day to keep the tension below 25 mm. Hg, and the patient is advised to lead as unexciting and regular a life as possible, avoiding spirits and coffee. Reading and cinema-going are permissible so long as the eyes do not feel strained or blurred. Progress is checked by testing the visual fields at intervals of one, two, or three months with a perimeter, and, if the field is contracting, a safety valve is produced by turning down a conjunctival flap and trephining a 2-mm. hole through the limbus—a small piece of iris invariably prolapses and is excised. In some patients, particularly the aged with traces of cataract, the disease may live up to its sobriquet, "the thief in the night," and contract the field to 10 degrees before it is detected. If the expectation of life is short this diminished visual field may be retained by pilocarpine or eserine drops, even if the tension remains above normal. A good life expectancy indicates operation, iridencleisis being preferred. However, no matter what operation is employed, 40% of eyes with wide-angle glaucoma get worse, some in spite of a normal tension and others because of the development of nuclear cataract.

Congenital Cataract

Congenital cataract may occur in one or both eyes and may range from a pattern of fine dots in the lens nucleus, allowing moderate vision, to completely opaque lenses. It may be familial, associated with the ridged teeth of defective calcium metabolism, or related to maternal rubella. No general agreement has been reached on the value of giving convalescent serum to pregnant women exposed to rubella, or on whether pregnancy should be terminated if the mother contracts the disease in the first four months.

Any baby after the first 12 weeks of life who pays scant attention to bright objects, or who has squint or nystagmus, should be examined ophthalmoscopically after administering 1% atropine sulphate eye ointment daily for a few days, when the pictures shown in Fig. 2 may be seen. If cataract is complete in both eyes operation is indicated as soon

FIG. 2.—(a) Congenital lamellar cataract. (b) "Bicycle-spoke" cataract, causing polyopia. (c) Nuclear cataract, causing "old sight." The areas shown white appear black against a red background when the eye is examined with an ophthalmoscope.

as the child is weaned. If the vision is good enough to allow the child to get about, operation should be deferred to the age of 2½ years, when surgical results are better. "Needling" has now been superseded by "linear extraction," in which most of the lens is removed by passing a keratome through the limbus into the lens itself and removing or expressing as much lens matter as possible by irrigation. Glaucoma or retinal detachment not infrequently supervenes in early adult life, so that one eye only is treated in this way, the other being kept in reserve. In 56% of congenitally cataractous eyes other obvious defects are present and the visual prognosis is poor. Even when apparently normal the central vision may remain poor after a successful operation owing to a (postulated) retinal dysplasia.

Acquired Cataract

Most of these cases are of senile—that is, unknown—origin. Cataract may be suspected when a patient of 45 or over complains (in addition to the usual reading difficulty) of monocular diplopia with bright objects, visual failure in the distance, or photophobia for which there is no external cause. In sexagenarians these symptoms may actually be accompanied by "old sight"—that is, ability to read without spectacles. With the ophthalmoscope the cataract can be seen as dark "bicycle spokes" or as a central haze against the red background (Fig. 2). In such cases ophthalmological examination is essential while a clear view can be obtained of the fundus to exclude glaucoma and macular degeneration. Later, when the cataract progresses, the fundus becomes invisible and its functional value uncertain until after operation.

There is no agreed medical treatment of cataract, and, as the problem approximates to unboiling a hard-boiled egg, this is not surprising. Nevertheless, provided that glycosuria and focal sepsis are excluded or treated, that adequate glasses are provided, that care is exercised in not reading when the eyes are tired, and that physical trauma is avoided—a jarring fall may mature a cataract—the changes in vision are usually slow, and most cataracts take 10 to 15 years to reach a point where extraction is required. That is to say, most never require operation.

Should a patient be told that he has a cataract? In some cases the patient's temperament makes this unwise, but in general, and provided the diagnosis is accompanied by adequate explanation, it is better to tell anyone complaining of increasing or persistent visual defect. Ultimately the search for the elusive "correct" glasses will end by the patient becoming aware of his trouble and believing it to be worse than it is.

Cataract extraction is performed under local analgesia. It was confined at one time to those cases in which the lens was "ripe"—that is, as opaque as "sunlight" soap—because autolysis of the translucent lens material remaining after extraction of the cataract by the extracapsular method (Fig. 3a) caused iritis. Of recent years greater risks have been taken with cataracts confined to the nucleus in patients over the age of 60, but post-operative iritis still occurs in 13% of cases. With the more recent and more difficult intracapsular operation, in which the lens is removed

in its capsule (Fig. 3b), the incidence of iritis is much lower, and the only criterion of ripeness is a physically and mentally fit patient is whether he has enough sight to carry on his business or, if retired, to read. It seems strange to find an eminently operable condition like cataract high on the list of the causes of blindness, but severe diabetes, hypertension, chronic bronchitis, or disabilities of temperament may render patients poor operative risks.

Myopia

Most of the blindness in myopia occurs from macular degeneration due to high myopia in late middle age. The patient usually complains of a dark central spot that remains fixed (not floating) at the centre of the sight, which indicates the final stages of macular degeneration. Whether the effects of such malignant myopia are of purely genetic origin and uncontrollable, or whether the wearing of the correct glasses, an education with a minimum of reading, and the administration of calcium by mouth exercise any influence in youth is uncertain. Most ophthalmologists adhere to these principles in the early treatment of such cases.

One form of blindness usually associated with myopia and susceptible to surgical treatment is detachment of the retina. The patient generally has moderate myopia and complains of floating black specks, flashes, or areas of light on moving the eye in the dark and, if the detachment is in the upper half of the retina, a defect in the lower visual field. Any patient who develops a spontaneous vitreous haemorrhage without obvious systemic cause should also be suspected of a detachment. A combination of any two of the above symptoms, particularly after a blow to the eye or head, requires a careful examination under homatropine mydriasis. If the grey area indicative of a detachment is found, the patient, unless obviously hopeless, is admitted to hospital as a surgical emergency and is nursed recumbent with both eyes bandaged to localize the tear (or tears) at the site of the initial detachment. If the detachment diminishes in size the prognosis is improved.

In 1929 Gonin showed that if a thermocautery is pushed through the sclera at the site of the tear the subretinal fluid leaves the eye and the resultant choroiditis round the site of the cautery puncture produces adhesion between the retina and choroid. In this way he was able to cure some 29% of all detachments. To-day by using electro-diathermy in a similar way we cure 43%. It is possible to carry classification further than this: in some young people with slight myopia and a small easily localized tear some 90% are cured, while large detachments in the aged with high myopia and large or multiple tears are almost incurable. It is essential that all detachments be treated as early as possible, for if they reach the macula the ultimate central vision is greatly reduced even if the retina is ultimately replaced. Detachments in aphakic eyes have a poor prognosis with the diathermy operation, but the more recent procedure of posterior sclerectomy, in which a strip of sclera 24 by 4 mm. is removed from behind the muscle insertion and underneath the area of greatest detachment, is proving effective in some otherwise hopeless cases.

In future all Social Security (health service) prescriptions obtained from chemists in New Zealand will carry an extra red label with the words "Keep all medicines out of reach of children." This is an attempt to reduce the number of deaths and illnesses among children who accidentally get hold of medicines. An original article in the *Journal* on ferrous sulphate poisoning in children recently (1951, 2, 1112) advocated various ways of lessening this risk in Britain, and suggestions were made in subsequent letters showing that doctors are well aware of the danger, but so far no official action has been taken in this country.

COAL AND CORTISONE

MAN-POWER IN A SICK SOCIETY

BY

FFRANGCON ROBERTS, M.D.

Consultant Radiologist to the East Anglian Regional
Hospital Board

The cost of the Health Service being usually expressed in money, we tend to forget that the only purpose of money is to buy labour and raw materials. If these are not forthcoming in sufficient amount money is of no avail. Medical labour, whether used directly in the treatment of the sick or indirectly in the production of drugs and equipment for their benefit, is drawn from a pool common to all forms of labour, including the part engaged in our export trade, upon which our survival depends. If this trade were to languish through shortage of raw material, rearmament, foreign competition, or other causes, it might be possible to transfer some of the workers thus rendered idle to the Health Service, but any improvement in the Service which might ensue would be more than counterbalanced by the deterioration in the standard of health due to the diminished import of food. Even if a satisfactory market for our exports continues, our standard of living will depend upon the maximum allocation of labour to industry. It is therefore of the highest importance to determine the optimum share of the national labour pool which can be spared for health and other social services.

While our relations with other countries are partly beyond our control, and therefore impossible to forecast, our future domestic circumstances can be predicted with some accuracy. The figures for total population and age distribution given in the *Report of the Royal Commission on Population*, 1949, tell us the number of mouths which will have to be fed, the man-power which will be available for production, and the social burden which the non-workers will cause to the workers. From these figures we can predict the changes likely to occur in the incidence of disease, and from the combined information we can deduce our ability in man-power to cope with it.

Table I shows the age distribution for England and Wales calculated from the figures given for Great Britain in the Population Report.

TABLE I.—Age Distribution, England and Wales, in Millions

Year	0-14	15-40	41-64	65 and Over	Total	Dependants per 100 Workers
1947	9.2	16.1	13.2	4.5	43.0	47
1962	9.3	15.0	14.9	5.6	44.8	50
1977	8.7	15.3	13.9	7.3	45.2	55

The Available Man-power

Taking 1947 as the starting-point, in 1962 workers will have increased by 0.6m., but the non-workers by 1.2m., made up of 1.1m. aged and 0.1m. children. Thus dependants per 100 workers will have risen from 47 to 50. In the following 15 years the situation will worsen appreciably, for the workers will decline by 0.7m., while a fall of 0.6m. in children will be more than offset by an increase of 1.7m. in the aged, bringing the number of dependants per 100 workers to 55. Even this underestimates the gravity of the situation, for in the first period the increase in workers is confined to those aged 41-64. While they are increasing by 1.7m. those aged 15-40 are declining by 0.9m. Industry

is therefore gaining in experience but losing in health and vigour. The loss of younger workers is already having its effect, for at the moment there are 400,000 industrial vacancies which cannot be filled. This predicament is far from temporary, for in the second period the older group will decline by 1.0m., while the younger group will recover by only 0.3m.—a slight gain to industry in health and vigour but a heavy loss in experience.

The Incidence of Ill-health

Age Group 65 and Over.—The rise in the aged of 0.9m. in the first period, followed by a further rise of 1.7m. in the second, making a total of 62%, will of course be reflected in a great increase in the incidence of diseases to which this group is prone. In a previous communication (Roberts, 1949), based on the latest figures then available—namely, those of the Beveridge Report—I estimated the increase between 1941 and 1971 at 50%. For mental illness, since, according to the Ministry of Health, 75% of patients are 65 or over, it follows that by 1977 the number of patients will have increased by 47%. Meanwhile, during the year ended December 31, 1949, overcrowding in mental hospitals increased from 12.2 to 14.0%—a fact which seems to suggest that the much-vaunted new methods of treatment are not keeping pace with the increase in incidence.

Age Group 41-65.—The older half of this group is associated with the incipience of degenerative diseases and of those, such as cancer, which run a prolonged course but are not classed as chronic sickness. Apart from the increase in incidence due to the increase in numbers, continued medical progress will effect a further prolongation in a state of invalidism, while an increasing proportion will survive to enter and swell the ranks of the aged. Between 1962 and 1977 this factor will diminish owing to the decline in numbers.

Age Group 15-40.—The fall of 1.1m. by 1962 will cause little easement, because this group is the least prone to ill-health.

Age Group 0-14.—By 1962 there will be little change; after that, a fall. Upon this group elaborate preventive measures are being lavished—antenatal and post-natal clinics and so forth. Yet although these have been in operation for some years there appears to be no sign that they are effecting any diminution in juvenile illness.

The overall prospect, therefore, is one of steadily mounting ill-health, but confined to the older members of the community.

Idle Dreams

Such, then, is the problem—a death-struggle between economics and morbidity, between national and individual survival—a problem which would be grave enough even if international relations were harmonious. How does the Ministry propose to solve it? The answer is to be found in the Ministry's memorandum entitled *The Development of the Consultant Services* (1950). This must be read in conjunction with the recently published Report for the year ended March 31, 1950 (Cmd. 8342), which shows the stage reached on December 31, 1949.

The purpose of the memorandum is to indicate to regional hospital boards their duties "against the background of the long-term organization of the Service." It deals with each class of disease in turn. In many instances requirements are based on hearsay evidence. The phrases, "It is said that...", "It has been suggested that..." occur again and again. The planners seem to have accepted without question the extravagant estimates submitted by representatives of each interest in turn. They express beds and man-power usually in terms of requirements for populations of 100,000-120,000; in the less common diseases for 1,000,000 or for a region. They make no attempt to add up the separate estimates so as to show the needs for the treatment of all diseases in the whole country. Had they done so the result might have surprised them. Adopting the axiom that the

whole is equal to the sum of its parts, I have taken the liberty of making good the deficiency by simple multiplication and addition. Since in some places the memorandum is not free from ambiguity the calculation has not been easy. I hope, however, that I have interpreted its meaning with reasonable accuracy, and I apologize for any mistakes. The result, together with the bed-provision existing at the end of 1949, is shown in Table II.

TABLE II

	Beds Allo- cated Dec 31, 1949	Total Beds Required	Total Senior Staff Required (Estimated as Full-time)	
			Consultants	Registrars
General hospitals:				
General medicine ..	33,739	97,700	1,170	1,170
General surgery ..	32,332	70,400	1,170	780
Unclassified ..	15,169

Diagnostic radiology ..			410	260
Grand total ..	475,544	755,000	11,353	5,072

a, Numbers not stated. b, Included in other beds. c, Includes chronic cases. d, "Assisted by such whole-time registrars and junior staff as may be necessary." e, "On the same lines" as d. f, These beds to be under general physicians.

Hospital Beds

Table II shows that beds of all kinds are deficient by nearly 300,000. In other words, existing beds need to be increased by 63%. General hospital beds need to be nearly doubled. The deficiency applies in varying degree to all diseases, with two exceptions—infectious diseases and chronic sickness. For the former ample provision is of course essential in order to meet epidemics, but the Ministry's view that the provision for the chronic sick is nearly sufficient is contrary to general experience.

From Table II an interesting calculation can be made. Deducting 35,000 beds closed for cleaning and redecorating, there will always be 300,000 general hospital beds in use. Taking 18 days as the average stay of each patient, each bed will be occupied annually by 20 patients. The population being 43m., this means that the Ministry expects one person out of seven to do his duty by spending 18 days in a general hospital every year. To these must be added the convalescents, those permanently or semi-permanently immured in mental, mental deficiency, tuberculosis, and chronic sick hospitals (for whom 420,000 beds are to be provided), the thousands in bed at home "with the doctor" (or without), and the hordes besieging general practitioners' surgeries and contributing to the 35.3m. attendances in casualty and out-patient departments. So much for a healthy nation.

Senior Staff

It might have been thought that estimates of future senior staff could be based only on figures showing the existing staff expressed as full-time labour. Such figures, however, are apparently not available. The report for 1949-50 enumerates full-time and part-time appointments, many of the latter being multiple. For instance, 1,310 whole-time and 12,372 part-time consultant appointments were held by 5,200 persons. On a similar calculation 686 whole-time and 2,891 part-time senior hospital medical officer-appointments involved 1,100 persons, giving a total of 6,300 persons. Since some of the multiple part-time appointments were collectively not full-time, we may take the full-time labour at about 5,000—that is, less than half the number required according to the memorandum. Registrars and junior hospital medical officers are given as 3,972 whole-time and 831 part-time. The amount of full-time labour of these grades employed in 1949 was therefore approximately the same as the amount which will ultimately be required.

More significant, however, is the consultant/registrar ratio. The overall ratio aimed at is about 2:1, but for some reason not explained it varies widely between 4:1 for ophthalmology and 2:3 for general surgery. One suspects that the planners have accepted the views of consultants given with no thought for the fate of their assistants. The ideal ratio should of course vary according to whether establishment is static or expanding, and according to the purpose of registrarships. If establishment is static and each consultant has one registrar of six years' tenure, he will have five registrars during his 30-years term of office. But, of these, only one will reach consultant rank. If establishment is expanding, a condition which can at best be only gradual and temporary, perhaps two will gain promotion. The system of registrarships is therefore workable only on the condition that the majority of the holders cannot expect to attain consultant rank. Whether this is just to them or in the best interests of medicine I do not propose to discuss. It may well be that a registrarship in general medicine is a good preparation for general practice, but the same cannot apply to plastic or thoracic surgery.

It was the belated discovery of this situation which led the Ministry in the autumn of 1950 to announce its decision drastically to reduce the number of registrars, recommending those discharged to seek employment abroad or in general practice. That this was to be the fate of some registrars was mentioned in the memorandum which we are discussing and which was published in the same year. But here comes the interesting point. The memorandum in almost identical form had been issued *confidentially* to regional hospital boards early in 1948. It contained this passage:

"In this memorandum the term 'registrar' is used in a generic sense where it is desired to suggest the employment of officers senior to the house-physician or house-surgeon and considered to be passing through a probationary period of training in a specialty. Some practitioners may start on such a career and, after a period of a year or two, turn to training in some other consultant field or to general practice. Others will continue, acquire a full period of training, emerge as consultants for more senior appointments on hospital staffs. It is not possible to estimate the numbers in either group, and as a result estimates of the numbers of registrars given in later sections include both these groups."

It would be interesting to know why the Ministry informed the predominantly lay regional hospital boards two years before it informed the medical profession.

Total Personnel

Table III shows the figures for non-medical personnel. With the medical staff the total came to about 220,000 reckoned as whole-time. Even so, nurses were short by 41,263 and midwives by 2,344. If we add 20,000 general practitioners, their secretaries, the pharmaceutical chemists,

TABLE III.—Non-medical Personnel, December 31, 1949

	Whole-time	Part-time
Professional and technical	13,271	5,311
Administrative and clerical	23,797	
Maintenance, transport, etc	26,210	
Regional headquarters staff	1,320	
Blood-transfusion centres	1,107	
Nurses	125,131	23,624
Midwives	8,888	969
Total	199,724	29,904

and the number, unknown but certainly very large, engaged in the medical trades we arrive at a total which forms a substantial part of the nation's labour force. If the additional 63% of beds were forthcoming, hospital personnel would have to be increased by 140,000, giving a total of 360,000. The truth, of course, is that this extra labour is not and will not be available, for the simple reason that it does not and will not exist.

Thus the authors of the memorandum live in a world far removed from reality. They show throughout no evidence that they recognize any economic limitations to their plans. Indeed, the only limiting factors which they admit are the existing shortages in buildings and trained specialists, but they confidently assume that these shortages cannot fail to be remedied in course of time. In a mood of joyful anticipation they portray the future in glowing colours—the future, that is to say, for hospital staffs. They envisage a kind of clinical *Republic* on the Platonic model in which the medical guardians work in ideal surroundings and are paragons of virtue and industry, exhibiting in perfection give-and-take, willingness to co-operate, and anxiety to improve their efficiency—qualities which, to do them justice, most of them already display without any Ministerial prompting.

But the facts must be faced. The numbers engaged in the Health Service must be determined, not by national needs, but by national earnings abroad. If these decline, the Health Service must suffer. If we want cortisone we must sell more coal. There is no other way. Those who wail against any cuts are crying for the moon, and politicians, to whatever party they belong, who promise that there will be no cuts are promising the moon. The advice which the Ministry is giving to hospital boards is therefore grossly misleading and a direct encouragement to extravagance. Even though the incidence of ill-health is destined to increase, long-term policy should be framed with the prospect of enforced contraction in view.

The point of immediate importance is the entry into the Service. The years quoted in the projections given above are not so far off as they seem. In 1962 those now entering medicine will be in the registrar stage, if it still exists, and in 1977 they will be at the height of their powers. Whether we like it or not, it is a logical corollary to the establishment of the Health Service that the State must control and reduce the intake of medical students to meet the economic future so far as this can be predicted, so as to ensure a balance between the treatment of ill-health and productive capacity. We cannot tolerate a situation in which youth in its thousands hammers at the doors of the medical schools while industry cries out for labour. The Health Service is no haven from the economic storms which will batter us, perhaps to pieces.

Certain consequences of this limitation should be noted. First, every year added to the duration of medical training reduces the number of persons effectively employed. For instance, 20,000 general practitioners are reduced by about 700. The same applies to study-leave, aggravated by the fact that this is invariably expansionist in effect. Apart from those branches of medicine in which exceptional skill and experience are required, is it really true that a person is not fit for independence and responsibility until he is in his middle thirties—that is, until half his life has been spent? Secondly, reduction in the number of the junior grades means that seniors will have to undertake many of the duties

from which they are now relieved. The latter will therefore have to be increased in number by raising the retiring age to 70.

Such, then, is the prospect as I see it. Four years ago in this *Journal* (Roberts, 1948) I asked the question, Where are we going? I still don't know, but at least I know where the Ministry wants us to go. To plenty in the midst of poverty; to a medical heaven in the midst of a bankrupt, bedridden, and hungry hell.

CONCERNING THE EPILEPTIC

[FROM A CORRESPONDENT]

A general practitioner with a list of 2,000 patients will probably have four or five epileptics under his care. These people will be handicapped in varying degrees by their fits, and by the attitude of mind about epilepsy of those with whom they come into contact. The social handicap is usually by far the greater burden.

In the public mind, epilepsy is associated with mental disorder. Now, while it is true that fits are common among mental defectives and the insane, most epileptics living outside institutions, apart from the occurrence of their fits, are essentially normal individuals, mental deterioration being unusual in those with only a moderate number of fits. Anomalies of temperament, however, are not uncommon: in some cases the temperament is affected by the disease, and the anomalies, like the fits, are a manifestation of the paroxysmal dysrhythmia of cerebral cells, but often temperamental changes are a secondary phenomenon, the result of social frustration. There is also a common belief that the outlook for an epileptic is necessarily bad. This is quite untrue. Many people who have had fits during childhood and adolescence become quite free of attacks in adult life, and in others the administration of drugs usually results in effective control or at least lessening of the fits.

The Harm of Concealment

The knowledge that epilepsy tends to run in families aggravates a common impulse to conceal the occurrence of fits. Concealment can only harm the patient and increase anxiety all round. The social handicap from the familial tendency to epilepsy can be lightened by frankly facing the facts. Even marriage, and the prospect of having children, may in some cases be quite justifiable for an epileptic if the prospective partner is shown to have a normal electroencephalographic record. Near relatives of an epileptic who have dysrhythmia of an epileptic type have the same chance of producing epileptic offspring as a frank epileptic.

Parents are often ashamed that a child of theirs should have fits, and are over-anxious about the occurrence of a fit in public. At school, fits may cause a great disturbance in the class, and as a result of this the epileptic child comes to be avoided by his fellows. An awareness that he is not wanted soon gives the child a strong sense of inferiority; he becomes desperately lonely, and takes on to himself the shame and anxiety shown by his parents. As a result of this unhappy train of events, the child's fits increase in number. An epileptic child should be allowed as much freedom as possible, even at some risk. Parents must hide feelings harmful to the child; they must take him about with them and treat him as a normal individual. Teachers and pupils at school must learn to regard fits as a natural occurrence, causing no special concern. Whenever possible an epileptic should have a normal home life and education, but if the child has a great number of fits, or his home conditions are bad, the school medical officer will arrange for his admission to a special school for epileptics. Here medical supervision can be more thorough than at home, and the child loses the feeling of being alone and inferior. Early advantage should be taken of institutional care when necessary.

Employment of Epileptics

During the war physically handicapped people previously considered to be unemployable were encouraged to train for essential work. Thousands of these took their places as wage-earners, and by April, 1950, the names of 15,078 epileptics appeared on the *Register of Disabled Persons*; of these, 13,563 were actually in work. This is particularly encouraging, as occupation and interest are direct anticonvulsants.

The task of finding work for an epileptic now officially falls to the disablement resettlement officer, who is guided by the report he receives from the patient's own doctor at the time of registration. However, continued supervision and encouragement by a social worker is often a determining factor in keeping an epileptic at work. Also knowledge of the patient in his home surroundings, visits to prospective employers, and consultation with the patient's doctor do much to ensure that the individual epileptic is placed in work for which he is most suited.

British Epilepsy Association

The British Epilepsy Association, formed in 1950 as a memorial to the work of Dr. J. Tylor Fox, aims at educating the public in the nature and social effects of epilepsy, and so help epileptics to take their proper place in the community. Parents of epileptics, or the patients themselves, often welcome the knowledge that their difficulties are understood and shared by other families. The association forms a unit of which they can become members. An attempt is made to find a solution to individual social problems. In addition, simple explanatory pamphlets have been published, designed to help parents and employers, and these can be obtained from the British Epilepsy Association, 7, Victoria Street, London, S.W.1.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Pethidine Hypersensitivity and Histamine

SIR,—In the last year there have been communications to the *Journal* describing severe hypersensitive reactions to pethidine.^{1,2} The possibility that pethidine might produce the symptoms of the hypersensitive reaction by releasing histamine is suggested by the observation that it causes a triple response on injection into human skin.^{3,4} This possibility is further supported by experiments demonstrating that the pharmacologically related opium alkaloids do actually release histamine.^{5,6} Also, the urticarial rash and oedema of the lips and eyelids following pethidine administration in the patient of Dr. E. B. Butler are strikingly similar to the signs occurring when histamine is released from the tissues of unanaesthetized dogs following administration of histamine-releasing drugs. I would therefore like to mention here results shortly to be published in detail which demonstrate that pethidine, under certain conditions, is an effective releaser of histamine.

It was shown that the intra-arterial injection of relatively small amounts of pethidine into an isolated, perfused preparation of cat's skin released large amounts of histamine. In the intact cat, intravenous injection of large doses of pethidine produced increased plasma histamine levels.

The clinical picture of circulatory collapse, urticarial rash, and facial oedema occasionally seen following pethidine may therefore well be due to the release of histamine in patients who, for an as yet obscure reason, release histamine much more readily than others after administration of this drug. Since mepyramine considerably mitigates the signs accompanying histamine release in response to a histamine-

releasing drug (although the histamine release persists),⁷ the antihistamine compounds may be effective agents in combating the rare but alarming hypersensitive reactions to this drug.—I am, etc.,

Allergy and Rheumatoid Arthritis

SIR,—The letter of Dr. R. W. Barter (January 12, p. 109) referring to the use of antihistaminics and a postulated condition of hypersensitivity in rheumatoid arthritis recalls the case history of a patient which may be of interest.

The patient, a girl aged 14 in 1932, commenced with a disturbance affecting most of the joints of the body, including the elbows, knees, wrists, and small joints of the hands. This consisted in sudden painful swellings of the joints, subsiding after a week and recurring at about monthly intervals. These attacks were repeated for about six months, and then a condition typical of rheumatoid arthritis followed.

The joint disturbance at the onset was not associated with any rise in temperature, splenic enlargement, or any systemic sign or symptom of note. The sudden onset of the swelling appeared to me at the time typical of that associated with angioneurotic oedema.

In addition to the usual antirheumatic therapy of that period, anti-allergic treatment consisting in calcium injections and injections of milk was given, with no benefit. It is possible that treatment with the modern antihistaminics would have been of use here. The patient at present presents all the features of an advanced crippled state of rheumatoid arthritis. Arthroplastic operations on both elbow-joints and knee-joints have recently been performed.

The mode of onset of the disease in this case, and the subsequent history, would indicate that a condition of hypersensitivity is associated with rheumatoid arthritis.—I am, etc.,

Manchester.

JACK CARR.

Acute Infectious Lymphocytosis

SIR,—In Dr. H. G. Dunn's very interesting article on acute infectious lymphocytosis (January 12, p. 78) he describes infestation with *Giardia lamblia* occurring at the same time and suggests this association is worthy of future investigation. I should like to add another case in which the two diseases appear to have coincided.

In August, 1951, a boy of 3 admitted to hospital for investigation of a congenital cardiovascular defect was found to have slight coryza and mild diarrhoea. Investigation of stools revealed many cysts of *Giardia lamblia*, and he had at that time a total leucocyte count of 49,000 per c.mm., of which 72% were normal small lymphocytes and 24% eosinophils. He was treated for five days with "atebrin," and after three weeks the leucocytes fell to 5,900 per c.mm. with 45% lymphocytes and 25% eosinophils, and no cysts or ova could be found. After another month the eosinophilia also had disappeared. There was nothing clinically to suggest glandular fever, leukaemia, or whooping-cough, and the child's subsequent history has been uneventful.

This case would thus appear very similar to those of Dr. Dunn.—I am, etc.,

Ashford, Middlesex.

JEAN M. WEBSTER.

SIR,—The article by Dr. H. G. Dunn (January 12, p. 78) prompts me to report two further similar cases recently seen.

These were brothers, aged 3 and 1½ years, admitted in November with a history of loose stools and vomiting for one day. No abnormality, apart from slight nasal discharge, was found on physical examination, but stool specimens from both children showed cysts and flagellate forms of *Giardia lamblia*.

White blood counts (W.B.C.) were: elder brother, total 83,600 (80% lymphocytes, 5% eosinophils); younger brother, total 85,600 (89% lymphocytes, 4% eosinophils, 1% monocytes). They were each given a short course of mepacrine, the diarrhoea settled, and the stools revealed no *Giardia* on several occasions. The lympho-

'PERNIVIT' FOR CHILBLAINS

Pernivit is an effective preparation for the treatment and subsequent prevention of chilblains. It utilises the vasodilator properties of nicotinic acid and the effect of vitamin K in maintaining normal blood coagulability and vascular permeability.

Itching and inflammation are quickly relieved. Dosage is from two to six tablets daily according to the severity of the case.

'PERNIVIT'

Pernivit tablets, containing Acetomenaphthone B.P. and Nicotinic Acid B.P., are available in bottles of 50 and 500.

Literature and specimen packings are available on request.

cytosis and eosinophilia persisted for several weeks, but the W.B.C. eventually returned to normal. Paul-Bunnell tests and Mantoux series were negative for each child. As in the other reported cases, no abnormal leucocytes were seen in the blood films (the excess being due to mature small lymphocytes), there was an absolute eosinophilia, and there was evidence of a mild upper respiratory tract infection (nasal discharge) in both boys.

It is interesting to note that the younger brother had been in hospital on three previous occasions with a history of diarrhoea: repeated stool examinations had then failed to reveal any *Giardia* and the W.B.C. was normal. Incidentally, the above are the only two proved cases of giardiasis found in this large general hospital in the last five years.

Although in Dr. Dunn's article and in the annotation (p. 96) doubt is cast upon the significance of the association between giardiasis and "acute infectious lymphocytosis," surely it is more than coincidental that this association was found in five of Dr. Dunn's six cases and in the two cases reported here, especially as Dr. Dunn himself states that "it is well known that *Giardia lamblia* may be found only after repeated testing of stools."

The fact that in some of Dr. Dunn's cases giardiasis was apparently present without a concomitant lymphocytosis can, I think, be discounted, as one could well postulate that in those cases the host and invading organism had achieved a state of symbiosis, whereas in those presenting with lymphocytosis and eosinophilia a temporary lowering of the host's resistance (as by the commonly associated upper respiratory tract infection) had allowed the giardia to become pathogenic.

Surely we should think of a relatively simple explanation such as this before attempting to create a new disease entity.—I am, etc.,

Bebington, Wirral.

MARGARET E. HALL.

Surgical Treatment of Sciatica

SIR,—In your comments on the surgical treatment of sciatica (December 15, 1951, p. 1448), having listed the results reported in certain large series, you go on to say that there are indications that the results are not in general so satisfactory, and as evidence of this you refer the reader to two reviews of compensation cases. I think it would be only fair to draw attention to certain details of these reviews. Both of the reviews deal only with cases treated prior to 1945, in the United States, and for this reason alone are hardly evidence of the present level of the surgical treatment of sciatica in this country.

The report of Aitken and Bradford (1947) deals with 170 cases operated on between 1940 and 1944: 67 patients had no disk lesion—i.e., 40% of the cases submitted to operation were wrongly diagnosed. In this regard the authors comment as follows: "It should be noted that we have included in the disk series all cases in which a disk is said to be found. There are several cases in which we had reason to question the findings." There were 10 cases of neurosis in the disk cases and 16 cases of neurosis in the non-disk cases, and in each instance there was ample evidence of such a neurosis before operation. Twenty cases were operated on within two months of the onset of the symptoms and some of these within one month. In some instances there were widespread explorations involving five or six vertebrae. There were five deaths. The complications included nine cases of sepsis, four of phlebitis, one of persistent headaches, two of post-operative drop-foot, and three of post-operative paralysis of the quadriceps. The authors are prepared to admit that the desire for financial imbursement influenced the end results.

The series reported by Marble and Bishop (1945) deals with 496 industrial cases, of which 92 had operative treatment. The diagnosis was confirmed at operation in 75% of these cases. Thirty-four cases are listed as having a good result, as they returned to normal work within six months, nine had fair results, being able to return to normal work within a year. It is said that the disability of the remaining 49 lasted for over a year, and in some the disability still continued. Presumably, in the other cases, the disability had disappeared and it would seem important to know when and in how many of the 49 cases the disability eventually disappeared. The fact that most of the failures occurred in cases which had been fused makes a true estimation of the results more difficult.

I doubt, therefore, if the reviews of compensation claims to which reference has been made justify the general state-

ment that "the results of operation are poor in many cases." It does not seem fair to point to the results of too exuberant surgery of about 10 years ago as indicating the poor results of surgery to-day. The important thing is to assess the results not of surgical treatment but of a single method of treatment in which both conservatism and surgery play properly assigned roles and to compare these results with the results obtained with the haphazard conservative treatment of low backache and sciatica 20 years ago.—I am, etc.,

Burton-on-Stather, Lincs.

DAVID F. THOMAS.

Specific Language Disability

SIR,—The annotation on the subject of specific language disability (January 5, p. 36) raises many important points and should be pondered deeply by all who are associated with learning children. These disabilities, as is stated, have long been recognized, and there is already an extensive but too little known literature on the subject. The most recent comprehensive work is Goldstein's *Language and Language Difficulties*, and perhaps the earliest is by Rosinus Lentilius, who, writing in 1698 in the *Miscellanea Medico-practica Tripartita*, tells of a left-handed epileptic girl who wrote with her left hand "*inveris literis*," which could be read only in a mirror.

There is no doubt that developmental aphasia, in varying degree, is the greatest single cause of backwardness in intelligent children—the children of whom school reports too often say, "This child could do better if he tried." The pathology is not yet fully clear, but it would seem that the commonest cause is crossed cerebral dominance, the emotional or psychiatric factor being secondary. It runs in families. To the spelling, writing, and reading difficulties in school must be added stammer, and, in everyday life, slowness in distinguishing left from right, impaired spatial orientation, poor skill in games with a small, fast-moving ball, and, in short, any activity needing speedy co-ordination of hand and eye.

Skilled remedial teaching, especially about the time the child is learning to read and write, is always indicated, and, if the subject is normally intelligent, usually successful. Unless such measures are taken, the backwardness remains and brings with it discouragement and a feeling of failure, which soon permeate all the child's attitudes.—I am, etc.,

London, W.1.

WILLIAM MOODIE.

SIR,—The annotation on specific language disability (January 5, p. 36) brings up a subject of considerable importance. Apart from the question of a possible neurological disorder, there are a number of interesting points about children suffering from this disorder which may throw light upon its nature. The first of these is the concreteness of their imagery.

I have had the opportunity to use non-verbal techniques in the study and treatment of a number of these children, and the improvement that has followed, both in writing and reading, suggests that it is unlikely that a fundamental neurological defect should be present in them, though there is nothing in what I have observed to militate against a possible familial grouping. The question, it seems to me, that arises is whether the condition is an exaggeration of the normal tendency to "concretize" perceptions, or whether the disability arises, as is suggested in your annotation, from some new factor.

Language, whether written or read, is basically a procession of abstract symbols to which we have agreed to attribute certain fluid meanings. I say fluid because it is the fluidity of significances of the same forms, in the English language particularly, which constitutes part at least of the difficulty of these children. To some children shapes drawn on paper or printed in a book have an exclusively concrete significance (as was beautifully illustrated in *The Wallypug of Why*, by G. E. Farrow, where the heroine goes for an excursion to the sea with the alphabet). No concrete objects have the same significance in all positions—an upright with a loop at the end is p in one, but becomes b in another, or even d if turned over. This is clear to us, but completely confusing to this type of child.

A second source of difficulty is the inability some children have of recognizing on their own initiative that the same sound, or

even the same shape of letters in a word, can have two (or more) entirely separated and different meanings. Most children grasp this spontaneously, but some do not, and the various meanings they hear attached to the sound or shape run together into a blurred confusion which makes it impossible for them either to recognize when printed, or to reproduce in writing, that word or phrase.

Considering how serious an effect this disability, if it persists, can have upon a child's practical future, it might be well worth while to set afoot some research on this point. Research in this case should be directed not so much to investigation of the efficacy of remedial teaching as towards study of the imagery of these children. If a child's imagery is very vivid and concrete, and his interest in the benefits of understanding abstractions is not aroused, my experience goes to show that a certain number of these children do not emerge spontaneously from this stage to develop a capacity for abstract thought; instead they become increasingly hopeless about their failure to grasp what is so obvious to their neighbours, and the help given them in remedial teaching, by its further emphasis upon abstract thinking, only increases their confusion.

Opportunity to express their ideas in concrete material can both give the observer information about the processes going on in the children's heads and give the children a possibility of sorting out their ideas without the, to them, puzzling intervention of abstract symbols. In my experience, when the confusion and hopelessness are lessened, appreciation of the meaning and use of symbols begins to dawn upon the children, and, if at this point good remedial teaching is given, in many cases normal reading and writing can follow.—I am, etc.,

London, W.11.

MARGARET LOWENFELD.

Meyer and Bleuler

SIR,—While fully supporting your reviewer's opinion (January 5, p. 32) that the translation of the late Eugen Bleuler's book *Dementia Praecox or the Group of Schizophrenias* is of great importance, I think he is mistaken in inferring that the late Adolf Meyer's conception of "reaction types" was in any way antithetical to the "pluri-dimensional" approach which developed in Europe on the basis of Bleuler's work.

From the early years of this century Meyer put Bleuler's views before American psychiatrists. In 1906 and 1908 Meyer put forward descriptions of a number of mental "reaction types" rather than "diagnoses," and at the same time wrote that every such abnormality had "its intrapsychic components (somatic disorders or disorders of special organs, including nutritional and histological disturbance of the nervous system) and components which are fully sized up only with psychological conceptions, either overt or substitutive." Meyer attracted Bleuler to read a paper to the opening of the Henry Phipps Psychiatric Clinic in 1913. There teaching from its opening was directed to the question, How much and what is structural, functional, somatic, metabolic, neurogenic, constitutional, psychogenic, social, etc., in any reaction? In tracing the evolution of the dementia praecox concept at the 1925 meeting of the Association of Research in Nervous and Mental Disease, Meyer stated that in his belief "the line of progress would lie in following the pluri-dimensional character of the facts involved." In the textbooks of his pupils the Meyerian attitude to diagnosis is summed up thus (Muncie, 1939): "The diagnostic formulation stresses factual statements of actual overt and implicit performance as action and reaction pointing out the principal and incidental disorders and how they have come about in a genetic-dynamic fashion . . . the formulations of empirical reaction sets of various sorts which are in no way mutually exclusive."—(Kanner, 1935): "Psychiatric diagnosis is a synthetic procedure and differs from non-psychiatric diagnosis by the virtue of the greater complexity and manifoldness of psychiatric symptoms . . . psychiatric diagnosis is a reformulation of the complaint on the basis of the available data . . . taking in the whole situation with its genetic-dynamic aspects, and speaks of the person rather than of his disease." Bleuler and his followers on the Continent were certainly dynamically and pluralistically oriented, but Meyer and all those he stimulated in America and elsewhere were also.

I think it is worth while mentioning these facts, as soon Meyer's collected works will be on the bookstalls for the

first time and it is to be hoped that they will be very widely read by young psychiatrists.—I am, etc.,

London, S.W.7.

W. CLIFFORD M. SCOTT.

Hypnosis and Asthma

SIR,—I would like to comment on the reply in "Any Questions?" (January 19, p. 173). The questioner asked, "Is there any evidence that hypnotic treatment can benefit sufferers from chronic asthma? What might be its danger, particularly with children?"

As I have been using hypnosis as a form of psychotherapy for bronchial asthma for several years, my own answer to part one of the question is strongly in the affirmative. In answer to the second part the reply given was, "The child may develop a habit of having anaesthesia, disturbance of memory, or tetany which may continue in the waking state." In a long experience dealing with many children I have never seen this happen. Children are good subjects for hypnosis and the results are excellent. In time this will be the method of choice in the treatment of this psychosomatic symptom.—I am, etc.,

London, W.1.

A. P. MAGONET.

SIR,—You have been kind enough to publish letters from me in the past (*Supplement*, March 12, 1949, p. 142; *Journal*, August 25, 1951, p. 497) dealing with the controversial subject of hypnosis.

Now that hypnotherapy has been accepted by the B.M.A. as a recognized medical procedure and semi-positive steps in the right direction have taken place to prevent the technique of hypnosis from being displayed on stage, film, and television, it seems absurd that the issue is still raging in the Press, radio, and television. I venture to suggest, and humbly of course, that had the medical authorities taken a more positive stand several months ago, and when stage hypnotism was obviously getting out of hand, the issue would now be clear cut and any legislation contemplated would have been easier to achieve. I would also suggest that even at this late hour, if a really positive attitude is taken by the profession itself, stage hypnosis, which is so obviously dangerous, degrading, and lowering to a recognized therapy used by many physicians, surgeons, and psychiatrists, would cease.

It is, of course, the medical profession which is largely to blame for this state of affairs. I have spoken to lay people who are appalled at the lack of interest displayed by the profession to the abuse of hypnosis by unqualified persons. It is not good enough to dismiss the subject by saying, "It's not important enough." It is important enough, as witness the constant barrage of rubbish written by, and to, the popular press on this subject. The public should be guided by a strong and understanding profession and not led by stage hypnotists and the Press to a knowledge of the subject.—I am, etc.,

London; N.15.

GORDON AMBROSE.

Are Neurotic Symptoms Imagined?

SIR,—Your leading article entitled "The Bottle of Medicine" (January 19, p. 149) was interesting and pertinent. But surely to describe symptoms as either "real" or "imagined" betrays a lack of understanding of modern psychiatric thought. No matter how convenient these terms may be, they should have no place in a serious discussion of neurosis. Can symptoms ever be unreal, outside frank malingering? The neurotic will not thank you for telling him that his pain, weakness, paraesthesiae and fears are unreal, and in fact he is liable to contradict you loudly by demonstrating his "imaginary" flatulence, breathlessness, or diarrhoea in unmistakable fashion.

One has often felt that some at least of the patients seen at psychiatric out-patient departments would be better treated by the general practitioner, as attendance at hospital seems to confirm them in illnesses which otherwise might

have been fleeting. It is recognized, however, that the G.P., even if he has the inclination and the knowledge, seldom has the time to treat neurotics. Moreover, as the powers that be are intent on reducing the registrar population, there is little doubt that the vast army of neurotics will shortly have no alternative but to be satisfied with the placebo and the pat on the head that were their portion in the bad old days when all illness that was not frankly organic was obviously imaginary.—I am, etc.,

Crichton Royal, Dumfries.

J. K. W. MORRICE.

Preventive Medicine

SIR,—I find myself becoming more and more exasperated by pompous statements, in the medical and lay press alike, exhorting the general practitioner to give more of his attention to preventive medicine and health education. One such nebulous utterance is included in a recent memorandum from the Birmingham Executive Council, while from Leeds comes the observation that "the Health Service shows a lack of balance between preventive and curative medicine."

Would it be an unfair question to ask of these arm-chair advisers what precisely they imply by the practice of preventive medicine by general practitioners?

Meanwhile I suggest that the balance must continue to weigh heavily on the curative side so long as there is a serious shortage of houses and hospital accommodation, food restriction, financial stress, unhappy marriages, and the like. Preventive medicine must inevitably follow in the footsteps of the slowly rising standards of society, depending for its more spectacular successes upon advances in medical research. At the same time I myself believe that the contribution of the general practitioner is much greater than is generally realized, since it is essentially of a subtle and individual nature and cannot be expressed—and heaven forbid that it should—in terms of "social medicine," "social therapy," and "group health."—I am, etc.,

London, S.W.7.

W. DYKES BOWER.

Shortage of X-ray Films

SIR,—Since I work in a chest clinic badly hit by the recent x-ray film shortage, I have read your leading article of January 12 (p. 94) and the subsequent correspondence with great interest.

I am firmly convinced that, unless present facilities for radiography of suspects and contacts are maintained and extended, long-term economy will not be secured. For instance, in this area the ultimate cost to the community of one or two missed early cases of tuberculosis may well be more than that of a year's normal supply of film.

Recent pronouncements from the Ministry of Health do not encourage me to believe that the supply of x-ray film will keep up with the ever-rising demand. If this is so, will it not be best to press for fundamental research into potentially superior radiographic methods rather than to resort, with a bad grace, to essentially second-rate or third-rate techniques, such as screen-photography of the mass radiography type, or even simple fluoroscopy?

I refer, of course, to the possibility of electronic enhancement of the brilliance of the fluorescent-screen image, so that instead of peering at dim outlines in darkened rooms we could examine a brilliant moving image of the living structures. Only an occasional 35-mm. photograph would then be required, for record purposes, and our demands for x-ray film would disappear overnight. This is, of course, the development at which Dr. A. Orley is hinting (January 26, p. 219). Research work in America has been reviewed by F. I. G. Rawlins (*Brit. J. Radiol.*, 1950, 23, 460), and since then I have impatiently awaited news of further developments towards what I would call "television screening." With this tool we could study living pathology where at present we are confined to still pictures or occasional glimpses at operation, and could confidently expect great advances in our understanding and treatment of chest diseases. Moreover, frequent nation-wide chest

screenings would become an immediate practical possibility. Since three-quarters of to-day's new cases of tuberculosis have been infected from unknown sources, discovery of these sources would soon enable us to break the back of the tuberculosis problem.

There is one awful possibility. While welcoming technical advances, I dislike any severing of the proper doctor-patient link. I shudder to think of the day when the diagnostician sitting at ease in his study will be able to talk to his patient over the "Tannoy" while observing him on ordinary television, switching over when desired to the x-ray television screening. Speedy and efficient, perhaps, but I still prefer the personal touch to the voice of this unseen new *deus ex machina*.—I am, etc.,

Leeds.

JOHN ASPIN.

SIR,—I suggest that an important factor in the unnecessary use of x-ray films lies in the fear of litigation. Practitioners must frequently call for an x-ray knowing that it is most unlikely to be of material assistance in the diagnosis; but they realize that should the case go wrong the admission that they failed to have an x-ray will weigh the scales heavily against them in the event of an action for damages. To neglect to do so is to go in the teeth of the advice frequently given by the medical defence societies.

It would be in the interests of national economy and a good thing for medicine if practitioners could feel free to exercise their clinical judgment and use x-rays at their discretion. I suggest, Sir, that the B.M.A. would be doing a service if it sought from the Ministry of Health an assurance that it would give its utmost support to a practitioner accused of negligence provided that he was able to show that he had exercised reasonable care and used his clinical judgment to decide that an x-ray was unnecessary (even though events showed him to be mistaken).

It seems urgently necessary for our courts of law to be made aware of the limitations as well as the uses of x-rays.—I am, etc.,

Horley, Surrey.

T. W. PRESTON.

T-piece Anaesthetic Technique

SIR,—I would like to make a few comments on Dr. John Bullough's excellent paper (January 5, p. 28) entitled "A T-piece Technique for General Inhalational Anaesthesia." As Dr. Bullough points out, the original T-piece technique was devised primarily for endotracheal anaesthesia in small children, and also for some intracranial operations. It is true that in my original paper an oxygen flow of only two litres a minute was recommended, but this was intended for very small and weakly infants, and subsequent experience caused me to modify the technique so that larger flows were employed. It is now my practice to administer nitrous oxide and oxygen in varying proportions through the T-piece with a total flow of four to six litres a minute. In cleft palate operations a flow of two litres of oxygen and two to four litres of nitrous oxide is usually combined with supplementary ether, and this will maintain a light plane of surgical anaesthesia with quite small amounts of ether over a long period of time. During the latter part of the operation the ether is reduced, or discontinued, so that when the operation is ended the patient should have regained consciousness, and will usually cry or phonate immediately the endotracheal tube is removed. I believe this is the experience of most anaesthetists who use the T-piece method.

In order to achieve the maximum success with the T-piece, two points are essential. First, the patient should be taken to the first or second plane of the third stage before the T-piece is connected, as it is essentially a method for *maintaining* a light plane of anaesthesia over a long period. Secondly, a length of tubing should be attached to the distal portion of the T-piece so that a small reservoir is formed in which the gases can collect. The length varies from eight inches for a 3-months-old baby, up to 18 inches or more in the case of an adult undergoing an intracranial operation. If this tubing is omitted obviously more ether will be required to counteract the large volume of air admitted

through the open end of the T-piece. Carbon dioxide accumulation does not appear to occur in clinical practice, probably because the gaseous mixture in the tubing is continually washed out by the relatively high flow of four to six litres a minute.

These comments are intended to clear up any misunderstanding which may have arisen concerning the original T-piece technique, and are in no way meant to detract from Dr. Bullough's very interesting paper, which may well prove to be a most valuable addition to our standard methods of anaesthetic administration.

In conclusion, I am surprised to read that Dr. Bullough considers the fitting together of the T-piece and a small length of rubber tubing to be cumbersome or tedious. In my younger days I am afraid that, when visiting other clinics, I have sometimes been guilty of slipping the apparatus in my pocket, in case (like the lady who took her harp to the party) I should be asked to demonstrate its use.—I am, etc.,

Newcastle-upon-Tyne.

PHILIP AYRE.

A Forgotten Tourniquet

SIR,—The fatal accident reported by your Medico-Legal Correspondent (January 26, p. 225) recalls to my mind a rule that should be universally adopted. For many years it was my privilege to administer anaesthetics for most of the orthopaedic operations performed both in hospital and in private by my late friend Mr. R. C. Elmslie and, through that connexion, several other orthopaedic surgeons. In so doing I was early assigned and willingly accepted the duty of applying the tourniquet when, as frequently, such a proceeding was required. From the first I adopted the very stringent rule that as I was the individual who applied the tourniquet I was the one person responsible for ensuring that it was not only loosened but entirely removed to a distance from the patient. I endured without complaint, and indeed with some satisfaction, the chaffing to which I was sometimes subjected for my fussiness in the matter. It is with the rubber bandage type of tourniquet that its complete removal from the operating-table is particularly necessary, as otherwise the loosening of the lower turns of the bandage only, though apparently adequate, may still leave sufficient obstruction to the free circulation by the upper turns to have serious consequences. It should be an accepted rule that it is the duty of whoever puts on such a dangerous appliance himself to remove it, or at least visually satisfy himself that it has been not only loosened but banished to a distance from the patient.—I am, etc.,

Esher.

C. F. HADFIELD.

SIR,—As long as the Esmarch rubber bandage is "hidden by the theatre gown . . . and by towels" (your Medico-Legal Correspondent, January 26, p. 225), for just so long will the risk of these nightmare tragedies of the forgotten tourniquet continue. The orthopaedic team must become as tourniquet-conscious as the abdominal team are swab-conscious. To this end, the routine adopted in the hospitals at which I work may be of interest. It is this:

1. For lower limb operations, a long Esmarch bandage is always used. Its free end is brought forward in a loose bight, and made fast with a clove hitch to one of the levers at the base of the table. It is felt that an attempt to drag the theatre table after the trolley of a departing patient would be a reminder.
2. The time of putting on the tourniquet is chalked up on the theatre blackboard or slate.
3. Before the patient leaves the table, the surgeon, his assistant, the theatre sister, and the anaesthetist must ask (or hear the answer to) the question, "Tourniquet off?"

—I am, etc.,

London, S.W.16.

JOHN IVES.

Xylocaine

SIR,—Your annotation in praise of "xylocaine" (January 26, p. 211) seeks to elevate this agent to the place of honour in epidural analgesia, and recommends a 1% or 2% solution for this purpose, alleging that the effects obtained with xylocaine are more certain than with other agents.

In a series of more than 400 cases in which epidural block was included in the anaesthetic technique for surgery below the diaphragm it has not been my experience that xylocaine was any more *certain* than other analgesic agents in suitable concentrations. Failures can occur with any drug used, but they are usually referable to faulty technique or equipment, and not to the drugs. Few would quarrel with the claim that xylocaine is swift in action; it is this speed of action which is often confused with greater certainty of effect. Other agents require up to 20 minutes to achieve a full epidural block. In the interval a surgical stimulus will elicit a response from the patient and unfavourable comments from the surgeon—an unhappy state of affairs that could have been avoided by inducing the block a little earlier. And so the anaesthetist who is behind schedule in an operating list will choose xylocaine rather than nupercaine or amethocaine, knowing that the former will more certainly produce a quicker block. But this does not mean that the final effect is more certain.

Furthermore, claims of ultra-long action (five hours or more) have not been substantiated, in my hands at any rate, when xylocaine is used in the epidural space. With concentrations of adrenaline between 1:250,000 and 1:150,000 the duration of action of a 1.2% xylocaine solution has been between two and a half and three and a half hours. An equipotent solution of nupercaine (1:600) has the advantage of a longer duration of action over a period of three and a half to four and a half hours.

Lastly, it is one of the virtues of the epidural technique that by it a differential spinal block is easily obtained, in which the more lightly insulated neural elements are blocked while the larger and more heavily myelinated motor nerves escape. Thus, while reflex flaccidity is achieved by interruption of the afferent pathways, the final common motor pathway is intact and intercostal respiration unimpaired by sensory and sympathetic blocks of the entire thoracic region. Xylocaine in strengths of 1% to 1.2% will provide such a differential block. The 2% solution that you mention in your annotation will cause a full paralysis of all afferent and efferent pathways in the segmental distribution of the block, and in doing so vitiates one of the great advantages of the epidural technique.—I am, etc.,

Emsworth.

P. R. BROMAGE.

Trichlorethylene Analgesia in Labour

SIR,—The opinion expressed by Mr. O'Donel Browne and others (December 29, 1951, p. 1556) and shared by your correspondent, Dr. O. Ll. Lander (January 12, p. 108), on the portability of Minnitt's gas-air apparatus was undoubtedly based on the original model, weighing 27 lb. (12 kg.). I feel attention should be drawn to the fact that the current model weighs only 12½ lb. (5.6 kg.), complete with cylinder, and is approved by the Central Midwives Board.—I am, etc.,

London, W.1.

A. CHARLES KING.

Male Infertility

SIR,—My intention when writing to you on the subject of male infertility (January 12, p. 106) was merely to point out to your readers, and especially to those who may be in charge of fertility clinics, that Roman Catholics, a considerable proportion of the population, experience serious difficulty when asked to supply a specimen of semen by the usual methods recommended. I am quite aware that the post-coital test is permissible on ethical grounds, but in my experience, in this country at least, this test is rarely mentioned to those seeking advice at fertility clinics. Furthermore, it is not quite as simple to perform as your correspondents would suggest. If it proves impossible to collect a specimen of semen by this method, then the only other method applicable to those who hold these principles is that of testicular biopsy.

It was not my intention to prove to your readers that masturbation is in fact a perversion, but to point out that

to help
your acne patient
get back
"in the swing"

'Eskamel' helps the young acne patient, worried about her appearance, to regain self-confidence quickly because:

1. 'Eskamel' is delicately flesh-tinted and masks unsightly lesions; moreover it harmonizes so well with the skin that it is virtually invisible in use.

2. 'Eskamel' is rapidly effective. It usually brings definite improvement—not in months or weeks, but in a matter of days.

'Eskamel'

a significant advance in acne therapy

Formula: Resorcinol 2%, Sulphur 8%, in a stable, grease-free, flesh-tinted base.

MENLÈY & JAMES, LIMITED, COLDHARBOUR LANE, LONDON, S.E.5

for Smith Kline & French International Co., owner of the trade mark 'Eskamel'

'DISTIVIT' B₁₂

brand

'Distivit' B₁₂ is a sterile aqueous solution of crystalline vitamin B₁₂, the most potent anti-anaemic substance known. Vitamin B₁₂ is highly effective in the treatment of Addisonian pernicious anaemia, including the neurological complications of the disease. Good responses in other types of macrocytic anaemia have been recorded. There are no known contra-indications to its use and there is no evidence that it gives rise to undesirable side-effects or to sensitization. 'Distivit' B₁₂ is issued in three strengths in ampoules containing 20, 50 and 100 micrograms per ml. in boxes of 5 x 1 ml. ampoules.

In Para-nasal infections **ARGYROL** provides
physiological action
without CNS stimulation
or rebound congestion

① A return to normal function by the decongestive, demulcent and bacteriostatic actions of ARGYROL is achieved without the side effects and rebound so frequent with many vasoconstrictors. In the solution of para-nasal problems, the ultimate advantages of using ARGYROL are readily apparent.

The ARGYROL Technique

1. The nasal meatus . . . by 20 per cent ARGYROL instillations through the nasolacrimal duct.
2. The nasal passages . . . with 10 per cent ARGYROL solution in drops.
3. The nasal cavities . . . with 10 per cent ARGYROL by nasal tamponage.

Its Three-fold Effect

1. Decongests without irritation to the membrane and without ciliary injury.
2. Definitely bacteriostatic, yet non-toxic to tissue.
3. Stimulates secretion and cleanses, thereby enhancing Nature's own first line of defense.

Decongestion and Relief without Rebound ● Decongestion without Dysfunction
— the medication of choice in treating para-nasal infection

COMPOSITION:

ARGYROL is a colloidal preparation containing 20% silver combined with alkali-treated protein to give solutions with a silver ion concentration near 10⁻⁸ m, a pH near 9, and a particle diameter between 1-10th and 1-100th that of Staphylococcus aureus.

*Argyrol is a registered trade mark, the property of the makers A. C. BARNES CO. NEW BRUNSWICK, N.J.

Sole distributors in U.K.:— **FASSETT & JOHNSON LTD. 86 CLERKENWELL RD., LONDON, E.C.1.**

Roman Catholics believe it to be so. I have no desire to use your columns for an ethical debate, but I would beg your indulgence to answer some of the points made by Dr. G. I. M. Swyer (January 26, p. 218).

It is not the principles and practice of Roman Catholic theology that are involved in discussing the problem of masturbation, but rather the conclusions which result, in the light of pure ethics, from a consideration of the natural law—i.e., the sum-total of all that our reason prescribes as necessary for the proper moral ordering of our lives. It would take up too much space to describe in detail the reasoning involved in determining the moral norm of the use of the sexual faculty, but any who are interested can consult textbooks of ethics written by abler pens than mine. Briefly, then, I would reiterate firmly that masturbation is a perversion of the sexual faculty, and its use is gravely sinful and not permissible under any circumstances. The questions of whether masturbation is used for the purpose of investigating fertility or whether or not pleasure is obtained by its use are quite beside the point. If the action is wrong the presence or absence of pleasure does not affect the issue.

I can assure Dr. Sawyer that no Catholic priest can sanction masturbation—no more than any bishop, archbishop, or even the Pope can alter the rulings laid down by considerations of the natural law.

I feel that I need hardly discuss Dr. Swyer's argument whereby he seeks to throw doubt upon the perversity of masturbation by pointing out, on eminent authority, that it is frequently indulged in by human males and monkeys. Come, Dr. Swyer, are the Ten Commandments or the laws of the land invalid because they are broken every day? Finally, Sir, I would apologize for the very brief and incomplete exposition of the ethical principles involved, but would repeat that those interested will find abundant literature on the subject.—I am, etc.,

Manchester.

F. N. VALDEZ.

Interesting Tumour of the Palate

SIR,—Simple tumours such as adenoma, fibroma, papilloma, and dermoid cyst are rare and only occasionally seen.

The patient was a woman aged 41 years with a four-years history of a small lump appearing in the hard palate region on the left side and gradually increasing in size. It was 1 in. by $\frac{1}{2}$ in. (2.5 by 1.25 cm.), ovoid, edge well defined, and consistence hard. It was attached to the mucous membrane by a short stalk. There were no other lumps present and no enlarged glands.

As it appeared benign and causing an ill-fitting denture it was decided we should remove it and send a section for pathological report. The patient was lightly anaesthetized and removal attempted with a scalpel, but the stalk proved too hard. However, a diathermy needle was used and the lump removed. Haemostasis was secured and the stump touched up with carbolyzed resin. The patient has had no further trouble.

Pathological Report.—Appearance, an oval hard mass 2 cm. in greatest width; incision shows a dense fibrous stroma. Sections show a purple submucosal fibroma with zones of calcification and occasional collections of chronic inflammatory cells. The appearances suggest a response to chronic irritation.

Since such simple tumours are rare we presume that this one was the result of chronic irritation over years, and it was large enough to cause trouble, hence removal was needed and was a complete success.—We are, etc.,

Honiton.

A. T. H. GLANVILL.
B. MARTYR.

Treatment of Tuberculous Meningitis

SIR,—After reading the article by Dr. S. Russell Jamieson (January 12, p. 83) on his cases of tuberculous meningitis I would like to make the following observations, as I cannot agree with his dosage of streptomycin, criteria for continued bed-rest, or the relation of B₁₂ and increase in weight in these cases.

The daily injections of streptomycin both intramuscularly and intrathecally for six months continuously may give the impression that this is a generally accepted scheme of dosage and in my opinion may lead to unnecessary over-treatment. It is well known that even to-day there is no general agreement on the

optimum dosage for these patients, owing to the difficulty in finding an adequate dose to cure the patient without producing toxic effects which may be avoidable: the tragedy of curing a patient yet leaving him stone deaf is only too common. Combined with this is our lack of knowledge about the development of drug resistance, although experience has shown that treatment is usually still effective long after resistance may have been expected to have developed.

I wish to emphasize that whatever principle of treatment is adopted the intensity and length of treatment are mainly determined by the response of the patient and not by an arbitrary dose decided on beforehand. Most authorities agree that an intensive course of daily injections is required until the patient shows a satisfactory response. This may occur at any time, often between the eighth and tenth week. After this has occurred a rest from daily intrathecal injections is both desirable, from the point of view of the patient, and quite safe, as the patient is under the closest observation should a relapse occur. It is again the patient's progress which determines the length of subsequent treatment, and, although most schemes employ daily or alternate daily injections with varying rest periods, it is of interest that recent views in this country and America suggest that twice-weekly injections may be just as effective as daily ones. Twice-weekly injections have indeed been used with satisfactory results on patients who have responded to the conventional daily dosage. It may well be the answer in avoiding the neurotoxic effects of streptomycin in the future.

It is well recognized that the protein content of the cerebrospinal fluid may remain raised for very many months, and, provided progress is otherwise satisfactory, it does not seem justified to keep the patient completely in bed until the C.S.F. is normal in this respect, though obviously the closest observation is required until this occurs.

I do not feel that Dr. Jamieson has made a convincing case for the association of vitamin B₁₂ with gain in weight in these patients, as a steady increase in weight occurs anyway when the patient is responding to treatment, and in the later stages is probably the most important guide to satisfactory progress.—I am, etc.,

Northampton.

C. J. ZERNY.

Technique of Shock Therapy

SIR,—Dr. D. T. Maclay mentioned Dr. A. Stephen and myself in his letter about the technique of shock therapy (December 15, 1951, p. 1464); Dr. J. L. Esplen (January 12, p. 109) suggests that this technique may be improved by the use of thiopentone. In view of these letters, and the association of my name with the first, I should like to set out some facts and express a few opinions about electroplexy modified by curare and other drugs ("flaxedil," decamethonium iodide, and "celocurin"). I hope shortly to write of this subject in a paper, the material for which has been collected for the past six years; in the meantime I should be sorry to see the defence of a valuable method neglected for want of a letter.

My colleagues and I have given doses of curare of between 5 and 15 mg. to the conscious premedicated patient on over 6,000 occasions. The premedication in use for the past two years has been hyoscine 1/200 gr. (0.3 mg.) and atropine 1/200 gr., given together. The incidence of breathlessness sufficient to cause complaint has been very low; it occurs sufficiently rarely to cause comment among the staff when it does happen. Other complaints of fears of various kinds are certainly not uncommon, but these are associated with any method of treatment, and do not bear any relation to the giving of a particular drug or injection. The patients who are most afraid are those suffering from obsessional and phobic disorders; a knowledge of the psychopathology of these diseases would seem readily to explain the frequency with which fear is a symptom in such cases. Some patients suffering from schizophrenia are also more apt to be frightened than the average patient. Melancholia is perhaps more commonly treated by electroplexy than are other diseases; in the straightforward case of melancholia it is our experience that complaint of breathlessness does not arise. However, endogenous depressive illness, occurring earlier in life, may show different characteristics. In the case of a Pole who, owing to his marked muscular development, received 15 mg. of curare, there was a severe reaction. He became panic-stricken—partly no doubt on account of the language difficulty—and a struggle ensued, in which he became cyanosed. This case was, however, exceptional in many ways, not the least in the size of the dose of curare.

It is not possible in the space of a letter to go into the reasons which prompt a psychiatrist to use curare, but it is pertinent to remark that in its use by us no deaths have occurred (though some patients were gravely ill physically and mentally) and only two known fractures were sustained (both crush fractures)—the circumstances under which they occurred being again quite exceptional. If the aim of treatment is to safeguard the skeletal system and yet give adequate treatment by electroplexy, then curare with premedication has seemed to myself and my colleagues to be adequate for more than three-quarters of our cases. Several hundred cases during this time have received thiopentone or other form of anaesthesia, but it seems inescapable that there is then an added risk, and there is certainly a greater expenditure of time by both nurses and doctors. In my view there is no doubt at all that thiopentone increases the danger of laryngeal spasm, particularly if it is not given in sufficiently large doses. It seems that the nervous patient is the one particularly likely to show vagal over-activity, especially after the onset of unconsciousness, when large-scale sympathetic over-stimulation due to fear probably comes to an abrupt end.

I would add that a distressed patient can very often be reassured effectively by being given between three and nine grains of sodium amytal by mouth at about the same time as the premedication is given by injection. So far as I know, this barbiturate given by mouth has no influence in producing untoward symptoms and may probably prevent them by inducing greater relaxation and calmness.

May I make a plea that electroplexy should not be called shock therapy? This is a most misleading term.—I am, etc.,
London, W.1. E. BERESFORD DAVIES.

SIR,—The letters of Dr. D. T. Maclay (December 15, 1951, p. 1464) and of Dr. J. R. Esplen (January 12, p. 109) lead me to anticipate what was to have been the subject of a later communication.

It appears desirable, on behalf of the patients about to be treated by electrotherapeutic techniques, to bring to wider notice the existence of new short-acting muscle relaxants which in my view so alter the principles of treatment that "straight" E.C.T. may be considered to be outmoded. I refer to the drugs described by Ottolenghi, Thesleff, Von Dardel, and Scurr which produce satisfactory relaxation for a minute or two and are therefore specially suitable for the purpose. By the kind action of the manufacturers experimental quantities of succinethonium iodide have been made available and have been found so valuable that uncomplicated cases can be treated as out-patients in about the time taken by straight E.C.T., with all the efficiency and muscle control of previous long-acting relaxants. It has been found possible to do away with the pre- and post-treatment atropine and oxygenation, and, since very much less than the usual dose of intravenous barbiturate (miscible with the relaxant, provided the mixture is used immediately) is necessary to cover the prodromal symptoms, the patient is awake within two or three minutes and movable within a few more. The net result is complete elimination of all the possible skeletal troubles, anxiety, restlessness, noise, and furor. Naturally it is early days yet to produce a statistically accurate, analysed statement, but, in the interest of patients everywhere, I will of course be happy to send details of the technique so far elaborated to anybody interested.

Incidentally, Dr. Maclay's letter gives a false impression of the frequency of bone fractures and other strains occurring in straight E.C.T.; with proper technique and reliable apparatus, accidents of this kind are almost unknown to-day.

I would add that I have been assisted very greatly in widening the field for these trials by the kind co-operation of Dr. E. B. Strauss, my chief, and Drs. D. O. Macaulay and J. Gould, my colleagues, in the Department of Psychological Medicine, St. Bartholomew's Hospital, Dr. J. F. Perredes, of the Lowestoft and North Suffolk Hospital, Dr. A. H. L. Baker, and others.

—I am, etc.,
London, W.1.

Gastro-duodenal Perforations

SIR,—The recent observations (see January 19, p. 164) on the subject of gastro-duodenal perforations are timely and of great interest. The following case gives some of the points that confront a surgeon in treatment.

A man aged 73 started suffering from peptic ulcer dyspepsia, with pains in epigastric area after meals (½–1 hour), relieved by powders; had constipation and reported attacks of vomiting food in January, 1950, when he was diagnosed as gastric ulcer and treated by medical means. His pains were controlled, but vomiting tended to increase in severity and frequency. No loss of weight and appetite good. In January, 1951, he perforated his ulcer, and was admitted into hospital, where the surgeon sutured a "perforated gastric ulcer." Further progress was satisfactory and he was discharged in February.

From February to December, 1951, the patient was free from all symptoms, gained weight, had a good appetite, and was well on his way to what he termed "complete recovery." During Christmas, however, his symptoms reappeared suddenly, with severe pains, vomiting, and loss of appetite. Investigations revealed a neoplasm of stomach. On January 8, 1952, laparotomy revealed an inoperable carcinoma of stomach covering the site of previous suture.

Thus, (i) The incidence of ulcer-perforation rises in the older age groups, and it is in these groups that carcinoma usually occurs. (ii) Perforation of gastric carcinoma is not very uncommon, the polypoidal and ulcerative type being particularly known for this complication. (iii) At the time of closure oedema and inflammatory exudate sometimes make it impossible to say if the ulcer is benign or malignant, and its exact site (viz., duodenum or pylorus) cannot be determined. (iv) About 5% of benign peptic ulcers which perforate and are sutured undergo a malignant change: this transformation is seen in the elderly group and is fairly rapid. (v) Biopsy in a doubtful case of perforation is not a routine procedure: even if it were carried out, the result may not be very conclusive in all cases. (vi) It would be interesting to work out the percentage of gastric carcinomata that first declare themselves as a perforation. (vii) Do any of these problems make the claim for partial gastrectomy at the time of first operation (provided the patient is in a fairly good condition), or, as in gastro-duodenal haemorrhage, at a later date, any stronger? (viii) It can be deduced that all patients past middle age who have a perforation sutured should be kept under constant observation, failing which a subtotal gastrectomy should be carried out a month after the suture. (ix) The conservative regime, in this elderly group, carries an obvious risk. (x) Is the mortality rate of partial gastrectomy in cases of gastro-duodenal haemorrhage (under "selective surgical intervention") any lower than that of a similar procedure in suitable cases of perforation?

—I am, etc.,

Orsett Hospital, Essex.

M. ISMET-ANWAR.

Nomenclature of Diseases and Operations

SIR,—A leading article in the *Journal of the American Medical Association* for December 8, 1951, deals with a new edition of *Standard Nomenclature of Diseases and Operations* and its relation to the *International Statistical Classification of Diseases, Injuries, and Causes of Death*. It points out that the two are by no means interchangeable: "The Standard system, as a clinical system, is necessary for the proper separation of individual differences in diseases for reading and research purposes," whereas "the International system applies mainly to much broader disease groupings for statistical purposes."

This difference has been emphasized since the International classification was adopted in my own H.M.C. area under the N.H.S. and has replaced the M.R. Classification I formerly used.

As the *J. Amer. med. Ass.* suggests, I find the new classification unsatisfactory for a number of purposes in which I am interested. It suggests that the World Medical Association might appropriately consider a combined clinical and statistical system, and perhaps you could bring your influence to bear on this if, as I think will prove the case, widespread adoption of the International classification is unsatisfactory for clinical purposes.—I am, etc.,

Hove.

W. A. BOURNE.

Obituary

W. S. HAUGHTON, M.D., M.Ch.

Professor W. S. Haughton, who died at his home in Dublin on October 12, 1951, will be missed not only within the medical profession, but also by a large collection of friends in sporting and musical circles.

William Steele Haughton was born in Dublin on September 26, 1869, the youngest son of Samuel Haughton, M.D., D.C.L.(Oxon), a Senior Fellow of Trinity College, Dublin, and a distinguished mathematician, geologist, and theologian. He was nurtured in the bosom of science and medicine, and was closely associated with Dublin University all his life. His formal education was undertaken at the Abbey School, Tipperary, and Portora Royal School. His early years at Trinity College, Dublin, were devoted to the study of experimental science, for which he gained a gold medal on graduation. When he graduated in medicine in 1894, he remained for five years as chief demonstrator in anatomy with Professor D. J. Cunningham. Within a matter of weeks of Röntgen reporting his discovery of x rays (1895) Haughton was operating a most primitive and fearsome tube and producing films which compare well with those taken to-day. No doubt his skill as an amateur photographer was of great assistance here. He was thus the pioneer of x rays in Ireland, and was honoured as president of the Radiological Society of Ireland from its foundation.

Haughton shared his father's interest in "animal mechanics," and this, enhanced by his personal background of experimental science, anatomy, and radiology, made bone and joint surgery his natural goal. His publications in the *Transactions of the Academy of Medicine in Ireland* indicate his early interests: they include "Mechanical Structure of Bone demonstrated by Röntgen Stereoscopy" (1901) and "The Healing of Wounds: Aseptic versus Antiseptic Methods" (1904). At the turn of the century he visited Kocher in Berne to study his aseptic technique, and at home he came under the influence of Swan, the pioneer who founded the orthopaedic hospital for children in Merrion Street. He was appointed an honorary surgeon to Sir Patrick Dun's Hospital in 1895, but resigned to undertake similar work at Dr. Steevens's Hospital in 1899. During the 1914-18 war he held the rank of major in the R.A.M.C., and worked in close co-operation with Sir Robert Jones, chiefly at the military hospital in Blackrock. During the second world war he continued at the orthopaedic hospital for children—working without his usual assistants, who were away on war service—and he carried through the task of removing the hospital from Merrion Street to more suitable premises in Clontarf.

At work Haughton was a painstaking surgeon, giving endless attention to detail, a rigid disciplinarian in theatre and wards, and yet held in affectionate esteem by patients and staff alike. From his earliest days he kept himself fit for surgery by regular devotion to outdoor pursuits. At college he was a keen oar and a skilled yachtsman. He was steeped in the lore of nature. Wildfowling and fishing of all kinds were his constant recreations. Sportsmanship was for him a struggle against a harsh opponent—Nature—in the form

either of a rough sea or a sagacious wild animal, and the fun was to overcome Nature by planning ahead to cope with every possible emergency. He was a born teacher, and gifted with a clear and emphatic exposition. He revelled in instructing both young and old, be it in the handling of a Thomas's wrench, a fishing-line, or a tiller, and the same thoroughness was given to each subject. The only pity is that he was not given to recording the results of his half-century of clinical experience in the form of scientific articles. This is an omission which perhaps his pupils may make good. Haughton was a Fellow of the British Orthopaedic Association and an honorary member of the International Society of Orthopaedic Surgeons. His work was recognized by his own university in 1923, when he was made honorary professor of orthopaedic surgery, and in 1936 he was granted the degree of M.Ch.

An ardent musician, he was possessed of a rich and powerful tenor voice. Frequently he was called upon to organize the musical programmes at college and professional functions, as, for example, during the Trinity Tercentenary Celebrations. As a lifelong friend of Dr. Marchant, the organist at St. Patrick's Cathedral, he was in close touch with all the musical activities there, and in leisure moments he was often in demand himself for a solo at medical dinners.

In 1909 he married Jane Eliza, daughter of the Very Reverend John Halahan, Dean of Ross, and a great granddaughter of Dr. John Halahan, a founder of the Royal College of Surgeons in Ireland. He is survived by his widow, a daughter, and a son.

SIR RALPH BIGNELL AINSWORTH, C.B., D.S.O.,
O.B.E., M.R.C.S.

(Major-General, A.M.S., ret.)

Major-General Ralph Ainsworth, formerly commandant and director of studies at the Royal Army Medical College, died in London on January 27, aged 76.

Ralph Bignell Ainsworth was the second son of the late Captain W. Ainsworth, of Lancashire. He was educated at St. Paul's School and St. George's Hospital, qualifying in 1899. In the following year he was commissioned in the Royal Navy as a surgeon, but he transferred to the R.A.M.C. in 1902. He was always keenly interested in hygiene and took the D.P.H. in 1907. While in India he served as special sanitary officer to the 6th Division (Poona). He was promoted captain in 1906, major in 1914, brevet lieutenant-colonel in 1919, lieutenant-colonel in 1924, colonel in 1930, and major-general in 1932. Throughout the first world war he served in France, and in 1919 he was in Russia for a few months. Three times mentioned in dispatches, he was awarded the D.S.O. in 1916, and, by the French Government, the *Médaille des Epidémies*. In 1923 he was appointed O.B.E. After a period of service in Egypt he returned to London as professor of hygiene at the Royal Army Medical College in 1928, and two years later he was made commandant and director of studies there, a post which he retained until his retirement in 1935, when he was appointed C.B. He then became director of medical services of the Joint War Organization of the British Red Cross Society and Order of St. John. His work during the second world war in this position was of the highest importance, and he was knighted for his services in 1946.

Ainsworth was a delightful personality, with great charm of manner and invariable cheerfulness. He

brought to all he undertook a very high sense of duty, and he was devoted to his Corps, which he served so long and faithfully. In 1903 he married Florence Gipsy, only daughter of Imre Kiralfy, of New York. The sympathy of his many friends and admirers will go out to Lady Ainsworth and his two daughters in their great loss.

Dr. A. MACBETH, of Owston Ferry, near Doncaster, died in Glasgow on December 10, 1951. Archibald Macbeth was born in Carradale, Kintyre, Argyllshire, on October 9, 1899. He was educated at New Cumnock School, Ayrshire, and was dux of his school; after winning a scholarship he passed on to Whitehall School, Glasgow, and remained there until 1917. He then joined up as a combatant at the age of 17. He was badly gassed in France when only 17½ years old, and was demobilized in 1919, when he became a medical student at Glasgow University, where he won several medals and prizes in both clinical medicine and clinical surgery. After graduating M.B., Ch.B. in 1924 he held one or two resident posts at the Royal Infirmary, Glasgow, and then became assistant to Dr. James Craig in Glasgow. He married Dr. Craig's daughter, Eileen Gillespie, she also being a medical graduate. Some time later Dr. Macbeth bought his own practice at King's Park, Glasgow, and remained there until 1933. After selling this practice he bought his last practice at Owston Ferry, and remained there up to the time of his illness. This latter practice was a large rural one and required much hard work. His services were always given unstintingly and he was extremely popular with his patients. He was indeed a very sound general practitioner and one who always put his patients first. He was of a quiet, retiring disposition, but he was always a regular attendee at meetings and lectures of the local Branch of the B.M.A. "Mac" had a very happy family life. He is survived by his widow, two daughters, and a son, to whom the deepest sympathy is extended.—W. H. B.

Dr. JOHN ISDALE GREIG, who was for 40 years in general practice in Kirkcaldy, died on January 6, aged 69. Before studying medicine at Glasgow University, where he graduated M.B., Ch.B. in 1905, he had taken the degrees of M.A. and B.Sc. After qualification he held the appointments of house-surgeon and house-physician at the Victoria Infirmary, Glasgow. He came to Kirkcaldy in 1911, where he remained for the rest of his life. As well as practising there he took an important part in local medical affairs, being honorary secretary of Kirkcaldy panel committee for 36 years, president of the Fife Branch of the B.M.A. from 1928 to 1929, and chairman of the hospital management committee of the East Fife group for a short time. He was also medical superintendent of the Hunter Hospital in Kirkcaldy. His ceaseless and untiring energy in his work won him many friends among the medical profession. During the first world war he served in the R.A.M.C. and was appointed M.B.E. for service in Africa. Dr. Greig was a keen sportsman, and was at one time president both of the Raith and Abbotshall Curling Club and of the Kirkcaldy Rugby Club. He is survived by his widow and three children. His son is a physician in Stornaway, and his younger daughter is also a doctor, and in fact assisted her father latterly in his practice.

In the obituary notice of Dr. GEORGE LESTOCK THORNTON (January 12, p. 110) mention has been made of his many years of distinguished service with the Ministry of Pensions. May one who knew him through those years express in some measure the affection and respect in which he was held by all his colleagues? Thornton was of the old school, distinguished in looks, courtly in bearing, gracious in manner. To him you were always a welcome and honoured guest, a valued friend. Should it be your lot

to disagree with him, he listened attentively, considered courteously your arguments, and with benign charm acceded here and dissented there. But rarely, if ever, did anyone convince him he was not right, and, whilst duly submissive to authority, none knew better than he how and when to go his own way. And rightly so, for the guiding purposes of his life had a broad charity and vision surpassing regulations. A most lovable man, distinguished in intellect as in heart, bearing good will towards all men, meeting good fortune with modesty and ill with tranquil courage, he was one whom to meet was memorable and whose friendship was precious.—A. S.

Dr. J. A. S. PURVIS, anaesthetist to the National Temperance Hospital and Samaritan Hospital for Women, died in London on January 19, aged 53. John Allen Spottiswoode Purvis was educated at Rugby School and went into the Army via the Royal Military Academy, Woolwich. During the first world war he served in France in the Royal Artillery and lost his right leg as a result of a wound received in 1918. He then took up the study of medicine, and graduated M.B., B.Ch. at Queen's University in 1925. Deciding to specialize in anaesthetics, he eventually became anaesthetist to the Samaritan Hospital for Women, the National Temperance Hospital, the West End Hospital for Nervous Diseases, and the Western Ophthalmic Hospital. At the time of his death he still held appointments at the first two of these hospitals. Those whose privilege it was to have his help in their work will miss his regular attendance, unless ill-health prevented, the care, skill, and good judgment which he brought to his duties, his consideration for his patients, and the feeling of support and co-operation which he gave to the surgeons. He made up for the loss of his leg by his interest in his garden, at his riverside residence, and in his car, which it was his pleasure to service. It was also his pleasure to entertain his friends on the river. His kindly, steadfast, and generous personality will be sadly missed, perhaps not least by hospital residents, to some of the less reverent of whom he was known as "Uncle John," and so-called to his face by a few. The sympathy of his many friends and colleagues goes out to his widow, Mrs. Barbara Purvis.—R. A. K.

The death occurred at Paignton on January 19 of Dr. JOHN PRINCE STALLARD in his 95th year. He was the son of Josiah and Susannah Stallard, of Worcester, and was educated at Rossall School and Edinburgh University, where he graduated M.B., C.M., in 1881. He proceeded M.D. in 1896. He was in general practice for many years near the centre of Manchester, and in addition held several hospital posts, including those of anaesthetist to the Victoria Dental Hospital, honorary surgeon at the Hulme Dispensary, and honorary physician to children at the Southern Hospital before and after its amalgamation with St. Mary's Hospital, where in his later years he took part in the obstetric practice. He published a number of papers on local and general anaesthesia, including one entitled "Removal of Haemorrhoids Rendered Painless by Injection of Cocaine" in this *Journal* in 1886. He retired in 1914 and went to live in the south-west of England. At the time of his death he had been a member of the British Medical Association for 70 years. He is survived by his second wife and by two sons, both doctors, one of whom has retired from practice.

The Services

Surgeon Captains M. Brown and J. H. B. Crosbie, R.N., have been appointed Honorary Physicians to the King.

Air Commodores F. E. Lipscomb and R. H. Stanbridge, O.B.E., R.A.F., have been appointed Honorary Physicians to the King in succession to Air Commodores C. T. O'Neill, O.B.E., and A. Briscoe, C.B.E., R.A.F., respectively, who have vacated the appointments on retirement from the R.A.F.

Chewing Gum *simplifies the treatment*

Prolonged local medication against penicillin-sensitive organisms, within the buccal cavity, is attained, easily and effectively, by the use of Chulin (Penicillin Chewing Gum A & H). The penicillin, incorporated in a new, improved and palatable mint-flavoured base, is brought into intimate contact with infected surfaces, providing an effective concentration of penicillin in the mouth for three to four hours.

Chulin is the simplest way of treating Vincent's infection, tonsillitis, pyorrhœa and other oral infections due to penicillin-sensitive organisms.

THE BIOLOGICAL ACTIVITY FACTOR IN DERMAL THERAPY

THE treatment of intractable skin diseases, operational trauma, burns, scalds, and bed sores with unsaturated fatty acids is normal. The physician knows that by no means all unsaturated fatty acids have therapeutic value; some are valueless. The factor to which the closest attention must be paid is the biological activity. The extraordinary history of success which has marked the introduction of F "99" in this country is very largely due to the fact that it possesses maximum biological activity. F "99" consists of a concentration of the biologically active isomer of linoleic and linolenic acids. For the first time is made available a standardized product of a purity and biological activity never before attained.

Composition

The active concentrate used in F "99" Capsules and Ointment is made exclusively from vegetable oils and contains the following proportions of unsaturated fatty acids:

Linoleic Acid	..	..	$C_{18}H_{32}O_2$ $\frac{2}{3}$
Linolenic Acid	..	..	$C_{18}H_{30}O_2$ $\frac{1}{3}$

Indications

The use of F "99" in capsule and ointment form is indicated in cases of infantile eczema, adult eczema, psoriasis, varicose leg ulcers, acne rosacea, furunculosis, etc. Administered under medical supervision, risk of complication is minimized to the point of extinction. In addition to its therapeutic action in treating skin disorders, F "99" ointment has proved of the highest value in facilitating the clean and rapid healing of trauma. It is also indicated in the treatment of burns and scalds—in fact wherever the restoration of healthy, unbroken skin is desired, F "99" ointment may be applied with complete confidence.

Professional Literature

F "99" has no National Formulary equivalent and is not advertised to the public. Every claim made for F "99" is supported by clinical evidence, and physicians who wish to learn more about F "99" are invited to write to:

ECONOMICS AND THE HEALTH SERVICE

THE NEW CHARGES

Mr. R. A. BUTLER, on January 30, moved that the House agree that measures should be urgently taken in all matters where action would benefit the overseas balance and the strength of sterling. He said he had made a full statement on the subject on the previous day and did not propose to speak again.

Mr. H. GAITSKELL examined the statement referred to by Mr. Butler critically. Touching on the cuts proposed in the Health Service, Mr. Gaitskell observed that he did not think there had been serious reactions to the charges previously imposed, which had left its cost at £400m. In making those charges the late Government was not attacking sick people. The Chancellor in his present proposals was discouraging people from going to the dentist to save their teeth. It was difficult to explain how there could be any saving if the dentists were to do the same work on the children. It was true that the Labour Government had proposed a charge of 1s. on each prescription, but that had been dropped largely through the administrative difficulty of levying the charge while old-age pensioners were exempted. That was the reason why the present Government was not exempting old-age pensioners. The charge was now to be levied on people who were sick and might find themselves in a state of great hardship. For such reasons the Labour Party would fight Mr. Butler's proposals.

Mr. P. THORNEYCROFT pointed out that the Labour Party had put a ceiling on the Health Service and that Sir Stafford Cripps had said that Parliament could not go on expanding one service after another but must absorb increases within a fixed total.

Mr. CLEMENT DAVIES asked whether Mr. Butler really thought that, when there was sickness in any house and prescriptions had to be written out, that was the moment for imposing charges, when there was probably less money available and more anxiety. He asked whether the charge was to be made on the first prescription or on every time the same prescription was used. To his mind this was the first retrograde step taken since the first national health service had been introduced in 1911. He suggested that Mr. Butler should look into the administration of the National Health Service in his endeavour to save £20m. Mr. Davies said he would be surprised if cutting out waste and extravagance did not save more than the £20m. envisaged by the Chancellor and produce a more satisfactory service.

Mr. A. BLENKINSOP said the Labour Party, when in office, had recognized the need to hold back hospital development because of the demands upon capital resources as a whole. Last year some of the unfortunate cuts which the Labour Government had to make in the health service had been more than balanced by increases in other parts. The charges in the ophthalmic service gave an opportunity for developing a service based on specialist investigation and advice such as was originally intended in the Health Service Act. He remarked that the proposal for a charge on dental treatments was a serious blow at an essential part of the preservation of the health of the people. Even if it were possible to increase the attention given to children's teeth a good deal of that attention would be wasted unless it was maintained at a later age.

In dealing with appliances the Labour Party had provided that such aids as surgical belts, hearing-aids, and so forth, were to be issued on the basis of a medical check by specialists. That was now apparently to be scrapped and a heavy charge imposed. He asked what was to be done to ensure that the war-disabled would continue to get free help of this character, as they had before the introduction of the health service. It was perfectly clear from the esti-

mates made by Mr. Butler of the yield from these charges that there must be many other charges which, so far, had not been mentioned.

The Doctor's Fee

The prescription charge had been proposed to correct the abuse which was apparent in the provision of drugs and medicines. There was still abuse in that field, but it had become clear to the Labour Party that it would be impossible to apply the charge, without hardships, to a vast number of people. It might deter a small minority who abused the service, but at the expense of a vast number who did not abuse it. The charge would make it more difficult for a doctor to see patients at the time when he desired them for an early diagnosis. What was needed was to make it easier for the doctor to give an honest judgment on needs, and that involved revision of the method of payments to medical practitioners. He was glad that discussions on that subject were being held, and he hoped these would establish a system of payment which would enable medical practitioners to give an honest judgment upon the medical needs of their patients. He noted the absence of any indication of concessions to the chronic sick—diabetics, and so on.

Sir IAN FRASER said he was certain that free medicine and free treatment had always been a fundamental mistake. The debate was resumed on January 31.

Purpose of Labour's Charges

Mr. C. R. ATTLEE then moved an Amendment to Mr. Butler's Motion, expressing disapproval of a tax on the social services and the other measures, many of which were irrelevant, unnecessary, and unfair. He said that when the Labour Government took action on the health service it desired to spend more on hospitals and less and less on other things, and the question then was not one of raising revenue but of restraining abuse and of getting a balance. The cuts now proposed were entirely different, deterring people from going regularly to the dentist.

Mr. ANEURIN BEVAN asked why the Conservative Party was trying to undermine the National Health Service. They had fought it, and now they were trying to destroy it. The National Health Service was crippled not only by the direct charges but by being unable to raise the ceiling of expenditure while the cost of living was going up. Therefore the country got more and more overheads, with less and less service to the patients. All the apparatus would be kept, but would be used less and less. The House should remember that large numbers of children were treated in the general dental service. It had always been the intention that the general health service should absorb the school dental service; because the general health service was more competent.

Hardship Among Workers

Mr. WILLIAM BLYTON asked whether the miner was to pay for any surgical appliances which he needed as a result of an accident in his employment. The National Insurance (Industrial Injuries) Act made provision whereby the Minister could provide for surgical appliances out of a fund under the Act. Those powers had not been used because of the operation of the National Health Service Act. Was the House to understand, now that the Chancellor intended to cut benefits under the National Health Service Act, that men and women in industry who needed medical appliances would receive them free under the Industrial Injuries Act?

Mr. JAMES GRIFFITHS said he understood that pensioners, men who were on sickness benefit, and men who had compensation would have to pay the prescription charge. So presumably would the man who was suffering from pneumoconiosis who went to the doctor for a prescription to help him over the first two or three hours every morning when he struggled for life. The Government was now discarding its pledges.

Mr. H. F. C. CROOKSHANK closed the debate. He said that by putting on charges in the Health Service Parliament

would in fact get a better-balanced scheme. If it happened to be cheaper it was not necessarily bad on that account. What the Government was doing was to get the priorities right.

Mr. Attlee's Amendment was rejected by 309 to 278, and Mr. Butler's Motion was carried by 306 to 275.

On February 1 Mr. H. F. C. CROOKSHANK introduced the National Health Service Bill, which was formally read a first time. (See *Supplement*, p. 47, for details of the Bill.)

HEALTH AND NUTRITION

NEED FOR BETTER FOOD

Lord DOUGLAS OF BARLOCH in the House of Lords on January 29 called attention to the incidence of illness and disability, and stressed the need for preventive measures, such as building up resistance by better nourishment. He spoke of the investigation made by the Pioneer Health Centre at Peckham before the war, which showed that out of 1,000 families only 10% showed no sign of bodily disorder, although 60 to 70% considered themselves to be well. This indicated that a National Health Service which proceeded on the principle of treating disease in those who sought medical attention would never raise the health of the people to a reasonably high level. His view was that unsuitable and insufficient diet was the main cause of sickness to-day. It was difficult to exaggerate the cumulative effects of chemical manipulation of foodstuffs, their contamination in handling, their poor quality, the abstraction from food of valuable nutritive elements, and the lack of balance in the diet of most of the population.

Lord CHORLEY said that the greatest contribution to positive health in the last few years has been the discovery of vitamins, but doctors were warned that these tablets were too expensive and that something cheaper must be prescribed. In a recent issue of the *British Medical Journal* there was an interesting article on the ordinary bottle of medicine. It was calculated that the nation spent £54m. a year on bottles of medicine which were of no value. If this sum were spent on vitamin tablets it would make a great deal of difference to the health of the community.

Aggenized Bread

Lord CHORLEY referred to the use of agene in bread, and said that many people, including Sir Edward Mellanby, thought this a dangerous addition.

Lord HORDER remarked that people were living longer and children were taller, heavier, and sturdier. The nation could not go on living longer and at the same time be faced with more sickness disability. What happened to the children was a good criterion. There was no evidence at present that the use of chemicals in food was a factor in the increased incidence of cancer, and he was satisfied that they could not trace to the use of agene any nervous complaint now prevalent.

Lord SEMPILL said that Dr. Badenoch, of Edinburgh, and Dr. Coghlan, of Hull, had shown the evils of the aggenization of flour. Dr. Coghlan had shown that since agene was introduced into flour in 1921 deaths from heart disease had risen rapidly and were still rising.

Healthier Children

Lord HADEN-GUEST regretted that no mention had been made during the debate of the work done by the school medical departments of the L.C.C. and other education authorities which carried out health examinations. Children now growing up were better developed and better balanced than children often had been in the past. He felt that the dangers which were supposed to be lurking at present had been overstated. There never was a time when the health of the people and particularly of the children had been better than it was to-day.

Lord ONSLOW, speaking for the Government, said the high rate of disability per 100 persons in the survey of

sickness included cuts, colds, and industrial accidents. The real rate was much lower. He pointed out that smallpox was hardly heard of now, and that since the immunization scheme introduced in 1942 the incidence of diphtheria had gone down. All parties in all Governments should share in the credit for the improvement which had occurred in the last few years. The high standard of health now enjoyed was largely due to the preventive measures introduced in this country and to the work of the local health authorities.

After Lord DOUGLAS OF BARLOCH had reaffirmed his conviction that the general diet at present was not properly balanced and had deficiencies, the motion was withdrawn and the debate closed.

Tuberculosis in Scotland

Mr. MALCOLM MACPHERSON drew attention in the House of Commons on January 29 to tuberculosis in Scotland. He said that in the post-war years there was a considerable increase in its incidence, but during the last two and a half years there had been a sharp decline in notifications, in deaths, and in the whole incidence of tuberculosis in Scotland. He was not sure whether the reasons behind that were even partly understood. He asked whether the use of B.C.G. should not be extended.

Commander T. D. GALBRAITH said the variations in the death rate from 1938 to the present day had been extraordinary. At present the policy was that there should be no general extension of the arrangements for B.C.G. vaccination. It was a supplementary provision, and not an alternative to existing preventive measures of local health authorities. During 1950 23,735 persons were tested with a view to vaccination, and 4,500 were successfully vaccinated. That continued on an increasing scale, but the value of the vaccine had not yet been satisfactorily scientifically established. Four mobile radiography units had been added to the two static units in Edinburgh and Glasgow, and another two would shortly be in operation—one in the west and one in the north-east of Scotland. An additional 1,173 beds had been provided in the last three years in hospitals and sanatoria, bringing the total number of beds for tuberculous patients to 5,967 on December 31 last. All but 286 of these beds were now fully staffed. Waiting-lists for admission to hospital had been reduced from 2,877 at the end of 1949 to 1,700 at the end of 1951. One hundred and eighty beds had been provided in sanatoria in Switzerland, and the first group of patients flown out was due to return to this country in March. The great majority of these would be fit to be discharged to their homes. In conclusion he affirmed that the Government intended to do everything possible to speed up the improvement which had recently been obtained.

Tribute to Lord Addison

In the House of Lords on January 30 Lord SALISBURY moved that the House adjourn as a mark of respect to the memory of the late Viscount Addison and in appreciation of his long and distinguished public service. He said such an adjournment was a very rare event, and the procedure had last been invoked in memory of his own father. Earl JOWITT, Lord SAMUEL, and Lord WEBB-JOHNSON were among those who spoke in support, and the motion was agreed to unanimously, and the House adjourned.

Fees for Cremation Certificates

Mr. JOSEPH REEVES moved on January 30 that leave be given to introduce a Bill relating to cremation and to purposes connected therewith. He said the Bill did not go beyond the proposals made by the inter-Departmental Committee which had reported in 1950. It proposed that the Home Secretary might, by regulations, prescribe maximum fees for the completion of medical certificates which the regulations required. This would be done after consultation with the appropriate medical authorities. Mr. Reeves

mentioned that whereas in 1902, when the Cremation Act was passed, 451 cremations took place in this country, in 1951 over 100,000 were registered.

The Bill was then read a first time without division.

Efficiency of the Health Service

Sir HERBERT WILLIAMS asked on January 31 what steps the Minister of Health proposed to take to restore the medical service to the people to the standard of efficiency which prevailed prior to July 1, 1948, in view of the heavy increase in mortality in the first three years of the service as compared with the three previous years.

Miss PAT HORNSBY SMITH replied that after allowing for relevant factors in each of the periods specified the difference in mortality was extremely small, and Mr. Crookshank was unable to accept the implication in the question.

Smoking and Cancer

Commander C. FLETCHER-COOKE asked on January 31 whether the attention of the Minister of Health had been drawn to the report of the Medical Research Council relating to the incidence of cancer of the lung among heavy smokers.

Miss PAT HORNSBY SMITH replied that Mr. Crookshank had been advised that there was not yet sufficient evidence of the exact relationship between heavy smoking and cancer of the lung to justify a publicity campaign. Further investigations were in progress.

Cortisone.—Special supplies of cortisone are being given by the Ministry of Health to hospitals for treatment of certain eye diseases, but the treatment of rheumatism is still a matter for investigation in which the M.R.C. is co-operating.

Ministry's Annual Report.—It is hoped that the Ministry of Health's next report will cover the 21 months from April 1, 1950, to December 31, 1951, and will appear before autumn, 1952. Thereafter reports will relate to calendar years and be issued more promptly.

Crematoria.—In England and Wales some 127 local authorities, or groups of local authorities, have applied for permission to build new crematoria since the war. No authorization has been given to any private company.

Medico-Legal

REFUSAL TO INCLUDE OPTICIANS IN LIST

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Two Glasgow ophthalmic opticians who had practised for 27 and 25 years respectively before the National Health Service (Scotland) Act, 1947, came into force applied for their names to be included in the Health Service list, but had their applications rejected. They therefore brought an action against the Secretary of State for Scotland and the Central Professional Committee for Opticians, on whose advice the Secretary of State acts in accepting or refusing applications, for a declaration that they were entitled to be included in the list.

Lord Sorn dismissed the action on the ground that the Court could not inquire into the way in which the committee prepared themselves to advise the Minister any more than it could into advice coming from his other advisers. The opticians appealed to the First Division of the Court of Sessions.¹ The First Division reversed Lord Sorn's decision.

The Court held that the Secretary of State had no absolute discretion to decide whether an optician who applied for inclusion in the list was qualified or not, but was bound to act on the committee's advice. That meant he must not act against the committee's advice. The Court could therefore investigate whether the committee had acted illegally by directing its attention to the wrong issue or by failing

to direct its attention to the right issue, or had acted oppressively by treating the applicants so unfairly and improperly that its finding must be set aside. The Lord President, in referring the action for trial, criticized the drafting of the regulations, which had inaccurately copied an English model. He said that it was enough for the disposal of the appeal to say that it was impossible to hold that there was not a case for inquiry.

This is a most important decision. It has established that, under the National Health Service (Scotland) Act at any rate, opticians who are aggrieved by exclusion from the list are not debarred from challenging their exclusion in the courts.

Universities and Colleges

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College held on January 31, with the President, Dr. W. Russell Brain, in the chair, Lord Moran was appointed representative to attend the Health Congress of the Royal Sanitary Institute to be held at Margate from April 22 to 25; Dr. Noel Harris representative on the Council of the National Association for Mental Health; and Dr. C. A. Keele a member of the Poisons Board.

The President announced the award of the Conway Evans prizes to Sir Gordon Holmes, F.R.S., and Professor S. P. Bedson, F.R.S.

The following candidates, having satisfied the Censors' Board, were elected Members of the College: H. Barcroft, M.D., R. A. Barker, M.B., S. Benaim, M.B., T. J. Bresnahan, M.D., D. J. Charley, M.D., R. S. Crow, M.B., P. S. Davis, M.B., F. E. Dische, M.B., R. A. Douglas, M.B., M. D. Eilenberg, M.B., M. G. Fitzgerald, M.B., A. Freedman, M.B., W. M. Fyfe, M.B., A. O. M. Gilmour, M.B., G. L. Glasgow, M.B., J. H. H. Glyn, M.B., G. J. Goldberg, M.B., J. H. Gough, M.B., C. H. Gray, M.D., O. P. Gray, M.B., Zaida M. Hall, B.M., J. I. E. Hoffman, M.B., K. Hugh-Jones, M.D., D. H. Isaac, M.D., A. M. Johnson, M.B., T. W. G. Kinnear, M.B., P. J. B. Landy, M.B., H. G. Ll. Lloyd-Thomas, M.B., Margaret R. Miller, M.D., J. Parkyn, M.B., Faith C. Poles, M.B., H. McL. Raffan, M.D., A. P. Roberts, M.B., G. A. Rose, B.M., I. P. Ross, M.B., Lieutenant, R.A.M.C., R. E. Rossall, M.B., J. T. Scott, M.B., G. B. Sinha, M.B., L. B. Strang, M.B., P. Strickland, M.B., D. Sutton, M.D., Brenda D. Van Leuven, M.B., F. W. Walton, M.B., W. R. Wardill, M.B., A. Wiener, M.B., J. A. C. Wilson, M.B.

Licences to practise were conferred upon 135 candidates (including 24 women) who had passed the final examination in medicine, surgery, and midwifery of the Conjoint Board and who have complied with the necessary by-laws of the College: A. C. D. Abdool Raman, L. D. Abrams, Pauline A. Adams, R. K. Alday, A. H. Askew, Margaret E. Atkins, Elizabeth R. Bakirgian, A. H. Barker, D. T. C. Barlow, W. G. Barry, F. J. A. Bateman, Bella Bernstein, Joan M. Bishop, A. S. Blake, H. M. J. Bogaerts, C. J. Booth, P. A. Bramley, Louise A. Brandram, D. W. Bray, L. H. Brearley, L. G. Brewster, A. MacD. Brown, C. G. Brown, Hilda M. Brunt, W. A. J. Bufton, C. V. Bullen, F. D'U. Burgess, T. K. H. Burnham, D. M. J. Burns, B. R. Carson, Stephanie J. Carter, C. E. Channon, A. R. Coshn, L. G. Couch, Barbara M. St. J. Coventry, E. Davies, Y. H. de la Bastide, E. M. Douglas, M. L. Ellis, J. R. Evans, A. Fairley, L. M. Fenton, K. Firth, Freda Fleischer, R. T. Gaukroger, A. H. Goodspeed, H. Graham, K. L. Granville-Grossman, Elizabeth I. Greenlaw, J. D. V. Griffiths, W. G. Griffiths, J. W. Hallewell, A. C. Helme, Josephine C. M. Heylen, J. B. Hickling, E. P. Hilary-Jones, J. A. Holmeyer, P. N. A. Holden, D. J. C. Horwood, D. J. Hosking, E. G. Hughes, M. M. Husainee, P. E. Kapff, S. G. Kent, G. A. Kerr, R. S. Lambie, A. V. Large, P. Iebon, I. Lenox-Smith, W. G. Lewis, W. H. McBay, D. A. F. McGill, C. L. Mansfield, G. A. Marin, Elsa M. Mellor, Morag J. R. Millar, J. A. S. Mitchell, Eleanor Morrison, E. A. Murray, Joan M. Newton, Margaret A. Norman, O. K. Ogan, H. B. O'Neill, P. B. M. O'Reilly, R. B. Parker, Gillian F. Peacock, F. O. P. Pearce, R. D. Pearson, B. J. Penry, Anne T. A. Phillips, D. W. L. Phillips, K. R. S. Pool, T. P. S. Powell, G. H. D'A. Power, Sylvia E. Prebble, J. H. Price, R. J. H. Pritchard, Anne M. Ranken, D. S. Robinson, J. Robinson, A. R. Roffe, B. H. Ross, E. M. Rosser, E. N. Rudland, G. J. Ryder, H. Schapira, G. G. Scott, Janet E. Sharp, N. E. Shaw, F. C. Shelley, A. Sladen, E. D. Sonnenfeld, G. B. Sparke, E. M. Sproston, F. Stacpoole-Ryding, Mary J. Starbuck, G. F. Stone,

¹ *The Scotsman*, June 9.

D. Stuart, G. V. Sutton, G. G. Tandy, Patricia M. Thompson, M. E. Tunstall, A. S. Viner, G. W. Waddy, R. S. Wambeck, R. W. Ware, C. D. Weeks, B. K. Wharton, G. T. Whitaker, D. C. Wilkins, D. F. Woodhouse, R. J. H. Xavier, J. E. York, S. A. A. Zaidi, L. M. Zinkin.

Diplomas were awarded, jointly with the Royal College of Surgeons of England, to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—A. F. Abdul-Kadir, M. E. Barry, A. B. Dick, C. E. Hartley, Hla Tin, Maung Lwin, J. H. McLaughlin, R. N. Nauth-Misir, A. B. Paltrinieri, F. J. Wickremasinghe.

DIPLOMA IN PUBLIC HEALTH.—J. P. Agrawal, Frances C. Myatt, T. A. Pace, A. C. B. Singleton, W. J. Smither, E. D. H. Williams.

Diplomas in Psychological Medicine, in Laryngology and Otology, in Medical Radiodiagnosis, in Medical Radiotherapy, in Anaesthetics, in Industrial Health, in Pathology, in Ophthalmic Medicine and Surgery, and in Ophthalmology were also awarded, jointly with the Royal College of Surgeons of England, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of January 19 (p. 168).

UNIVERSITY OF OXFORD

The following degrees were conferred in Congregation on January 24:

D.M.—M. Weatherall.

B.M.—J. D. Abrams, M. L. Harris, R. G. Tucker, S. B. Furnass, G. J. Renwick, H. E. Emson, I. A. Hill, J. R. Billinghurst, M. J. A. Menagé, D. E. P. Jones (in absence).

Notices of University scholarships, fellowships, studentships, and prizes are printed in a *Supplement* to the *Oxford University Gazette* dated January 30. The list includes a number of scholarships, etc., of interest to medical students and practitioners.

UNIVERSITY OF CAMBRIDGE

Applications for Berkeley Bye-Fellowships for research in (a) medicine, or (b) any branch of natural science, excluding medicine, should reach the Registrary, Gonville and Caius College, Cambridge, by April 1. Candidates must be male and not less than 26 years of age. The tenure of the bye-fellowship is from one to three years and the emoluments are from £500 to £1,000 according to standing.

The following degrees were conferred in Congregation on January 26:

M.B., B.CHIR.—*M. W. A. Haward, R. F. Ingle, G. W. Pearson, *A. P. Blower, *D. M. J. Burns, *D. Churchill-Davidson, *A. Paneth, *L. P. Sheil, *J. A. J. Smith, *A. C. Beatty, *D. L. Harrison, *J. F. Higgins, M. J. F. Courtenay, R. T. Gaukroger, *K. E. K. Rowson, *K. J. Martin, *P. F. Plumley, *J. L. Somervell, J. D. M. Howat, *R. Keeley, *N. A. Miles, *C. W. Savile, *R. L. Huckstep, G. S. Banwell, *P. H. Swinhoe, *H. M. Gough, *J. W. E. Mark, *A. A. El Nakeeb, *K. A. Taylor, H. Gough-Thomas, G. P. Greenhalgh, E. B. D. Hamilton, *J. F. Andrewes, R. V. Fiddian, T. F. D. Oram, G. T. Whitaker, *J. C. B. Fenton, *Mrs. Christine M. Maxwell, Mrs. Gwenhwyfar Cole, Alison M. Harington, June M. Phillips, P. S. Greaves.

*By proxy.

UNIVERSITY OF LONDON

The title of Professor of Biochemistry in the University has been conferred on Walter Thomas James Morgan, D.Sc., F.R.S., in respect of the post held by him at the Lister Institute of Preventive Medicine.

Vital Statistics

Infectious Diseases

The chief variations in the number of notifications of infectious diseases in England and Wales during the week ending January 19 were increases in scarlet fever by 156 and dysentery by 119, and decreases in acute pneumonia by 187 and whooping-cough by 45.

A small rise in the incidence of scarlet fever was reported from every region except the northern, where a small fall occurred. The largest fluctuations in the returns for whooping-cough were rises in Warwickshire 66 and Yorkshire North Riding 34. There were 11 fewer notifications of diphtheria than in the preceding week; the chief feature

of the returns was a decrease of 3 in Cambridgeshire. Large fluctuations were recorded by a few counties in the number of notifications of measles, although the total for the country was only 12 less than in the preceding week. The largest fluctuations were a decrease in Staffordshire of 75 and Cheshire of 73, and a rise of 46 in Warwickshire.

The number of notifications of acute poliomyelitis were 8 fewer for paralytic cases and 7 more for non-paralytic cases than in the preceding week. The cases were more widely spread and involved 25 counties, compared with 19 in the previous week. The largest returns were 3 in each of the counties of London and Kent.

Two fresh outbreaks of dysentery were reported from Wales during the week: Glamorganshire, Cardiff C.B. 22, and Pembrokeshire, Haverfordwest R.D. 12. A further 52 cases were notified from the outbreak in Norwich C.B., a rise of 21 above the total of the previous week. The other large centres of infection were London 56 (Islington 12, Fulham 10); Devonshire 45 (Exeter C.B. 23); Lancashire 58; Yorkshire West Riding 28 (Leeds C.B. 10); Middlesex 25; Southampton County 20 (Portsmouth C.B. 14); Surrey 16; Leicester 15 (Leicester C.B. 10); Durham 15; Kent 13.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1942-50 are shown thus -----, the figures for 1951 and 1952 thus ————. Except for the curves showing notifications in 1951 and 1952, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Protective Covering

It has taken æons for the armadillo to develop an armour that gives comparative immunity to the perils that lurk in the jungles of the Amazon.

The modern ulcer patient is more fortunate. Almost immediately, Gelusil* Antacid Adsorbent coats the inflamed or ulcerated areas of the gastric mucosa against injury by the acid gastric juice. At the same time, Gelusil provides swift relief of symptoms through the physical adsorption of hydrochloric acid by aluminium hydroxide; magnesium trisilicate prolongs the antacid activity through chemical reaction. Constipation, so frequently associated with ordinary alumina gels, is absent with Gelusil tablets and Gelusil does not interfere with the absorption of minerals such as calcium and phosphorus from the diet. Finally Gelusil is both economical and palatable.

FORMULA— Each tablet contains Mag. Trisil. 7½ grs. Alum. Hydrox. gel 4 grs.

NO WARNER PREPARATION HAS EVER BEEN ADVERTISED TO THE PUBLIC

William R. WARNER and Co., Ltd., Power Road, London W. 4.

LHC is made from New Zealand milk lamb intestines, thoroughly cleansed and frozen within two hours of the animal being killed, thus reducing to a minimum the growth of bacteria.

Scotland in 1949

Chief causes of death in Scotland in 1949 were heart disease, cancer, cerebral haemorrhage, and tuberculosis in that order, according to the *Annual Report* of the Registrar-General. Almost a third of all the deaths were due to heart disease; the death rate from cancer was 185 per 100,000 of population—four above the rate for 1948.

The infant mortality rate for 1949 of 41 per 1,000 of population was the lowest figure ever recorded in Scotland. It compares with a rate of 51 in Eire, 43 in Canada, 32 in England and Wales, 31 in the U.S.A., and 20 in Sweden.

The number of deaths registered in Scotland during 1949 was 63,488—an increase of 2,509 compared with the previous year. This gives a death rate for the year of 12.3 per 1,000 of population, 0.5 more than the rate for 1948. A comparison between the number of road accidents occurring in 1949 and in pre-war years shows an improvement. In 1949 there were 517 deaths compared with an average of 704 in 1931-5 and 653 in 1936.

Deaths from the principal epidemic diseases were 569, an increase of 205 over the previous year, chiefly because of an increase in deaths from influenza and whooping-cough.

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in December, 1951, was 99, compared with 117 (revised figure) in the previous month and 116 for December, 1950. Of these deaths 26 were underground in coal mines and 15 were in building operations.

The following cases of industrial disease were notified during the month: lead poisoning 1, epitheliomatous ulceration 7, chrome ulceration 10; total 18. There were no deaths (*Ministry of Labour Gazette*, January, 1952).

Week Ending January 26

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,293, whooping-cough 2,573, diphtheria 27, measles 2,837, acute pneumonia 836, acute poliomyelitis 27, dysentery 547, paratyphoid fever 10, and typhoid fever 2.

Census Changes.—Population figures obtained at the 1951 census show that there are now 160 great towns (population over 50,000) in England and Wales instead of 126, and 17 principal towns (population over 30,000) in Scotland instead of 16. Therefore the 1952 figures for deaths, births, and stillbirths in these countries, published weekly in our Table, cannot be accurately compared with those for 1951, which are printed in italics. The 160 great towns in England and Wales have a population about 10% higher than in the 126.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending January 19 (No. 3) and corresponding week 1951.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Medical News

First Appeal to Privy Council.—Dr. A. J. Daly has lodged an appeal with the Judicial Committee of the Privy Council against the decision of the Medical Disciplinary Committee of the G.M.C. to erase his name from the *Register (Supplement, December 15, 1951, p. 264)*. This is the first appeal to be made under the Medical Act of 1950, which made appeal possible against decisions of the Disciplinary Committee.

A New Quarterly.—*Laboratory Investigation*, a quarterly journal of technical methods and pathology, sponsored by the International Association of Medical Museums, will be issued this spring. Edited by a board appointed by the council of the association, the journal will be devoted to publication of the experimental techniques, original investigations, and observations in the basic medical sciences. It will cover papers dealing with pathology, histochemistry, cytological and histological methods, tissue culture, electron microscopy, radioactive tracer methods, museum techniques, objective teaching methods, photographic and injection methods, cardiac anomalies, teratology, and comparative pathology. *Laboratory Investigation* will be published by Paul B. Hoeber, Inc., Medical Book Department of Harper and Brothers. Subscriptions will be \$8 per year in the U.S.A. and countries of the Pan-American Postal Union, \$8.50 elsewhere. Subscriptions and inquiries for advertising space should be sent to the publishers at 49, East 33rd Street, New York 16, New York.

Catalogues of Micro-organisms.—The Canadian Committee on Culture Collections of Micro-organisms has published a directory and catalogue of collections maintained in Canada. A loose-leaf volume has been adopted to enable rearrangement and additions to be made. A directory of collections and list of species maintained in the United Kingdom and Crown Colonies has also been prepared. Details may be obtained from the secretary of the United Kingdom National Committee on British Commonwealth Collections of Micro-organisms (38, Old Queen Street, London, S.W.1).

Emergency Bed Service: Applications and Admissions.—During the seven days ending February 4 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,240, of whom 81.29% were admitted. A white warning, indicating that the percentage of admissions fell to 82½, was issued on February 4.

COMING EVENTS

Course on Chronic Rheumatic Diseases.—A concentrated week-end course, with lectures, ward rounds, and practical demonstrations, is being held at the Rheumatism Unit of St. Stephen's Hospital on Saturday and Sunday, March 29 and 30. The course is being opened by Sir Adolphe Abrahams, whose subject will be the rheumatic diseases in relation to general medicine. Details may be obtained from Dr. L. Cudkovic, Rheumatism Unit, St. Stephen's Hospital, S.W.10.

Study Tour in Italy, 1952.—The Italian Hospital Federation has invited the International Hospital Federation to hold a study tour of hospitals in Italy this year. The tour will begin in Milan on Sunday, May 25, and will end in Genoa on Saturday, June 7, including visits to hospitals and allied establishments at Sondalo, Brescia, Sirmione, Bologna, Florence, and Rome. It is open to all members of the Federation and their families in the first instance; non-members will be able to take part only if numbers allow. The registration fee will be £1 10s. for members of the I.H.F. and for each member of their families, and £2 10s. for non-members. The total cost has not yet been estimated. Details may be obtained from the Federation, 10, Old Jewry, E.C.2.

Strasbourg Summer School.—A summer school on "the healthy family" will be held at Strasbourg, France, from August 6 to 20. The course is intended for teachers, nurses, health visitors, social workers, and all who are interested in the family as the basic social unit and in the factors conducive to its physical, mental, and spiritual health. The cost will be approximately £32, which includes registration, second-class travel from London and back, full board and lodging in the university hostel, and tuition. Further inquiries should be addressed to the Secretary, British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1.

IV Interamerican Cardiological Congress.—The congress will be held in Buenos Aires from August 31 to September 7. Those who wish to participate in it as titular members should apply before April 1. The fee is \$250 (pesos). Members wishing to give communications must send before April 1 by way of the national society of cardiology to which they belong (or directly if there is no society of cardiology in their country) a summary of each work that must not exceed 200 words, and, if possible, written in Spanish or Portuguese and in English. All the correspondence should be addressed to the Administrative Secretary's Office of the Congress, Larrea 1132, Buenos Aires.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday

INSTITUTE OF PSYCHIATRY, Maudsley Hospital, Denmark Hill, London, S.E.—February 11, 5.30 p.m., lecture-demonstration for postgraduates by Dr. E. Stengel.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—February 11, 8.30 p.m., "Assessment of Therapeutic Trials," discussion to be introduced by Professor A. Bradford Hill and Dr. F. Avery Jones.

OXFORD UNIVERSITY—At Radcliffe Infirmary (Neurological Library), Oxford, February 11, 5.30 p.m., Film: "Embryological Development of the Eye," by Dr. George K. Smelser (New York).

Tuesday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 12, 5.30 p.m., "Growth of the Human at the Time of Adolescence," by Dr. J. M. Tanner.

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 41, Queensgate Terrace, London, S.W., February 12, 8.30 p.m., 5th ordinary meeting of 55th session. "Starvation," discussion to be opened by Sir Jack Drummond, D.Sc., F.R.I.C., F.R.S. Illustrated with lantern slides.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 12, 5.30 p.m., "Lupus Erythematosus," by Dr. B. Russell.

INSTITUTE OF PHYSICS: SCOTTISH BRANCH.—At The University, Glasgow, February 12, 7 p.m., "Electron Microscopy," by Dr. V. E. Cosslett, F.Inst.P.

MANCHESTER MEDICAL SOCIETY: SECTION OF SURGERY.—At Large Physiology Theatre, Medical School, Manchester University, February 12, 5 p.m., "Portal Circulation," by Professor R. Milnes Walker.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—February 12, 5 p.m., "An Interpretation of Statistical Trends in Tuberculosis," Milroy Lecture by Dr. V. H. Springett. (See also February 14.)

Wednesday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 13, 5.30 p.m., "Mycology—Allergy and the Serological Diagnosis of Fungus Infections," by Dr. R. W. Riddell.

INSTITUTE OF PHYSICS: SCOTTISH BRANCH.—At The University, Edinburgh, February 13, 7 p.m., "Electron Microscopy," by Dr. V. E. Cosslett, F.Inst.P.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., February 13, 4.30 for 5 p.m., "Bladder Growths," by Mr. R. Ogier Ward.

MANCHESTER MEDICAL SOCIETY: SECTION OF PATHOLOGY.—At Physics Theatre, Medical School, Manchester University, February 13, 4.30 p.m., "Some Aspects of the Pathology of Infantile Toxoplasmosis," by Dr. E. G. Hall; "The Diagnosis and Treatment of Congenital Toxoplasmosis," by Dr. A. Macdonald.

PHYSICAL SOCIETY: COLOUR GROUP.—At Institute of Ophthalmology, Judd Street, London, W.C., February 13, 3.30 p.m., 65th science meeting. "An Experimental Study of Colour Preferences," by Dr. G. W. Granger.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow.—February 13, 5 p.m., "*Myasthenia Gravis*," by Professor Andrew Wilson.
ROYAL SANITARY INSTITUTE, 90, Buckingham Palace Road, London, S.W.—February 13, 2.30 p.m., "*Port Health Control*," discussion to be opened by Dr. H. C. Maurice Williams.
SCIENTIFIC FILM ASSOCIATION.—At Meverstein Lecture Theatre, Westminster Medical School, Horseferry Road, London, S.W., February 13, 5 p.m., film show: (1) "*Cardiac Output in Man*"; (2) "*Blood Cells*."

Thursday

ALFRED ADLER MEDICAL SOCIETY.—At 11, Chandos Street, London, W., February 14, 8 p.m., "*The Aims of Therapy*," by Dr. James Moore.
BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 14, 5.30 p.m., "*Methods of Research in Industrial Medicine*," by Dr. Donald Hunter.
● HUNTERIAN SOCIETY.—At Savoy Hotel, Strand, London, W.C., February 14, 7 for 7.30 p.m., annual dinner.
● INSTITUTE OF CHILD HEALTH, Hospital for Sick Children, Great Ormond Street, London, W.C.—February 14, 5 p.m., "*Burns*," by Mr. A. B. Wallace.
● INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 14, 5.30 p.m., "*Histopathology of Bullous Eruptions*," by Dr. H. Haber.
LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—February 14, 8 p.m., ordinary meeting. "*Some Problems in Dermatology*," by Dr. R. M. B. MacKenna.
ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—February 14, 5 p.m., "*An Interpretation of Statistical Trends in Tuberculosis*," Milroy Lecture by Dr. V. H. Springett. (See also February 12.)
ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—February 14, 5 p.m., "*Swellings of the Neck in Childhood*," Hunterian Lecture by Sir Lancelot Barrington-Ward.
ROYAL INSTITUTION, 21, Albemarle Street, London, W.—February 14, 5.15 p.m., "*Respiratory Pigments*," by Professor H. Munro Fox, F.R.S.
ST. ANDREWS UNIVERSITY.—At Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, February 14, 5 p.m., "*The Child's Heritage*," by Professor J. L. Henderson.
ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—February 14, 4.30 p.m., lecture-demonstration in psychiatry by Dr. L. T. Hilliard.

Friday

EUGENICS SOCIETY.—At 26, Portland Place, London, W., February 15, 5 p.m., "*The Genetics of Mental Deficiency*," Galton Lecture by Dr. J. A. Fraser Roberts.
FACULTY OF RADIOLOGISTS.—At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., February 15, 2.15 p.m., Radiodiagnosis Section Meeting. "*The Lateral Position in Chest Tomography*," by Dr. George Simon; "*Carcinoma of the Middle Lobe Bronchus*," by Dr. G. Brian Locke.
● INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 15, 5.30 p.m., "*Lupus Erythematosus*," clinical demonstration by Dr. B. Russell.
● INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 15, 5.30 p.m., "*Pulmonary Stenosis*," by Dr. Paul Wood.
KENT AND CANTERBURY HOSPITAL, Canterbury.—February 15, 8 p.m., clinical meeting.
OXFORD UNIVERSITY.—At Magdalen College, Oxford, February 15, 5 p.m., "*The Neurophysiological Basis of Mind*," Waynflete Lecture by Professor J. C. Eccles, F.R.S.
ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—February 15, 8 p.m., "*Addiction*," by Mr. G. B. McAulay.
UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—February 15, 5.30 p.m., "*Some Recent British Contributions in the Field of Pharmacotherapeutics*," by F. Bergel, D.Sc.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At Hammersmith Hospital, Duane Road, London, W., February 15, 8 p.m., clinical evening.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Laws.—On January 29, 1952, at Sheffield, to Dr. Pamela Laws (formerly King), wife of Dr. John W. Laws, a daughter—Susan.
Lowe.—On February 3, 1952, at Simpson Memorial Maternity Pavilion, to Barbara (formerly Barlow), wife of Dr. R. C. Wilson Lowe, Hillwood, Clermiston Road, Edinburgh, a son.
Priest.—On February 3, 1952, at Leamington Spa, to Marianne (formerly Burgess), wife of Dr. Michael Priest, a daughter.
Stradling.—On January 31, 1952, to Dr. Peggy Snow, wife of Dr. Peter Stradling, a son.
Whalley.—On January 25, 1952, at Newcastle-upon-Tyne, to Joy (formerly Brooks), wife of Dr. G. Hamilton Whalley, twin brothers for Bruce—David and Peter.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Attempted Suicide

Q.—In the event of a patient being seen, examined, and thought to be a possible case of attempted suicide is there a responsibility on the medical practitioner to notify the police of his suspicions?

A.—The attempted suicide problem is a fairly common one, and raises an important issue on the fundamental relationship of mutual trust which is so important in general medical practice. It is true that attempted suicide is a misdemeanour, and that if information were laid to show that an attempt had occurred the police would have to make inquiries and could, if the evidence were sound, make a charge at the magistrates' court. Little advantage would ensue either to the accused or to the police—and the spectacle is depressing.

No statutory obligation exists to force a doctor's hand in the matter, and the general practice (which has the tacit approval of the law) is for the doctor to treat, rather than report, his patient's unhappiness. A form does exist in the Metropolitan Police stations which asks a hospital to which an attempted suicide has gone for treatment to report the day of anticipated release. This is not obligatory—it is merely a request which forms a part of the police action already set in motion. It can hardly be ignored, but to reply to a request for information is not the same as to volunteer a breach of the confidence the patient has a right to expect of his doctor. Neither doctor nor hospital authority need start an inquiry.

A History of Repeated Miscarriage

Q.—A woman of 42 has had seven pregnancies, with two normal children, four miscarriages, and, in the last pregnancy, a mongol who died shortly after birth. She wishes to have more children. Does this kind of history suggest that future pregnancies are likely to end by miscarriage or perhaps with an abnormal child? How should she be advised?

A.—If other causes have been excluded there is a real possibility that the abortions were due to malformations of the foetuses. At any rate the history is very suspicious, and, bearing in mind that the advanced maternal age also increases the risk, the chance of foetal malformation in the next pregnancy may well be very high. It is impossible to assess the risk accurately without more details about the abortions. The patient should be told that the history suggests that if she embarks on pregnancy she has a much greater than average risk of abortion and foetal malformation, but that a normal child is not impossible. The decision about further child-bearing is then a matter for the couple in question.

Fits from African Worms

Q.—What African helminthic infestations can give rise to Jacksonian epilepsy in man? How are they excluded?

A.—Epileptic convulsions may arise from infection with *Schistosoma haematobium* and from cysticercosis (*Taenia solium* infection). The latter is rare in Africa. Infection with schistosomes can be escaped by avoiding exposure in infected water; *Taenia solium* infection by avoiding undercooked pork. The diagnosis of schistosomiasis is made by finding the eggs in the urine or the faeces. Skin sensitivity reactions may help to confirm the diagnosis. The diagnosis

of cysticercosis may be difficult. It is important to establish the history of possible exposure. Excision and examination of the subcutaneous nodules which may be present may lead to the identification of the larval stages of the worm. It may be necessary to examine the whole body, including the head, by radiographs in order to identify the shadows of calcified cysts.

Boy or Girl?

Q.—A well-developed healthy child was noticed at birth to have no scrotum. The child is now 3 months old. The penis and prepuce are well developed, slightly larger than usual for the age, but the skin posterior to the penis is smooth, and shows a slight dimpling in the middle line with a faint outline on the skin suggesting a vulva. No testes can be felt. How should the sex be established? What treatment is advised?

A.—If there was a maldevelopment of the penis and urethra, such as hypospadias, one would be more concerned with the possibility of pseudohermaphroditism. As, however, these appear to be normal it seems more likely that the condition is one of congenital defective or delayed development of the scrotum. In such a case I have seen the scrotum develop adequately after daily local injection of 1 g. testosterone ointment (containing 25 mg. testosterone propionate to the gramme) for several weeks. If a scrotal sac is thus developed, it is not unlikely that the testicles will descend into it, but if not injections of gonadotrophins might be considered at a later stage.

Speaking more generally, if the sex is in doubt, the only sure way of establishing it is to do a biopsy of the gonads. Where they are not externally palpable an abdominal laparotomy will be necessary.

Multiple Myelomatosis

Q.—What are the latest views on the aetiology, treatment, and prognosis of multiple myelomatosis?

A.—It is generally agreed that multiple myelomatosis is a malignant neoplasm arising in bone-marrow, histogenetically related to the myeloid leukaemias and to the lymphoid tissue tumours. The cell type involved is believed to be an abnormal plasma cell. As in malignant disease generally, the aetiology is unknown, and there is no satisfactory evidence that chronic infections, trauma, or exposure to any known irritants act as predisposing factors.

Multiple myelomatosis is always progressive and fatal. The average duration of life is three years, but some cases survive 10 years. Spontaneous remissions lasting several months may interrupt the progress of the malady, and in some cases the patients can lead almost normal lives for a large part of the course. Death is usually due to complications such as renal failure, chronic urinary infection supervening on compression paraplegia, intercurrent respiratory infections associated with chest deformities and multiple rib fractures, progressive anaemia, and sometimes haemorrhagic states.

There is no specific treatment. Apart from the treatment of the various symptoms as they arise—for example, excision of growths encroaching on the spinal cord and nerves with resulting relief of paraplegia, or chemotherapy for intercurrent infections—radiotherapy offers the best chance of relieving pain, and may be given repeatedly in short courses to successively painful sites. When the pains become generalized and no longer within the scope of radiotherapy, some patients gain temporary relief from such drugs as stilbamidine isethionate, urethane, oestrogens, nitrogen mustards, and radioactive phosphorus, the use of which requires close supervision, but in most cases these substances are of little help and may induce unpleasant side-effects. The particular circumstances of each case require careful consideration before prescribing a course of one of these drugs. Thus stilbamidine is said to be most effective when given in conjunction with a low-protein diet, which is clearly not desirable for a debilitated patient. Stilbamidine is also contraindicated if renal func-

tion is impaired, which is frequently the case. The injections cause sweating, tachycardia, and vasodilatation, and a common delayed effect is anaesthesia of trigeminal distribution. Stilbamidine is therefore best avoided until other methods have been tried. Urethane may be given orally for long periods but often causes depression, anorexia, nausea, and vomiting. Like nitrogen mustard and radioactive phosphorus it induces leucopenia, and when these drugs are used repeated blood counts, including differential leucocyte counts, are a necessary accompaniment of treatment.

NOTES AND COMMENTS

Fatal Wasp Stings.—Dr. A. M. WOOLMAN (Switzerland) writes: In the answer to the question on wasp stings ("Any Questions?" November 17, 1951, p. 1231), treatment with ephedrine or isopropyl-nor-adrenaline and an antihistaminic is recommended. It does not appear to be widely known that the intravenous injection of a calcium salt can be as dramatic in affording relief as the injection of a preparation of the adrenaline type. In view of the dangers associated with intravenous injections of adrenaline derivatives, this method deserves wider recognition. Continental doctors are more calcium-minded than British doctors, and several reports on the calcium therapy of bee, wasp, and hornet stings have appeared in Continental literature. Some striking cases are described, for instance, by Schapschal, Serjakoff, and Kifaloff (*Schweiz. med. Wschr.*, 1940, 70, 374). They employed the double salt of calcium gluconate and calcium lactate, and recommend intravenous injection of 10 ml. of the 10% solution.

OUR EXPERT writes: In my answer I emphasized the value of adequate subcutaneous adrenaline and intravenous aminophylline in the treatment of severe anaphylactic (allergic) reactions to wasp stings. The literature to which Dr. A. M. Woolman refers can be read in a summarized form in English in "The Emergency Treatment of Bites and Stings with 'Calcium-Sandoz,'" issued by Sandoz, Ltd. (Switzerland). The results recorded are certainly quite striking, as Dr. Woolman points out. The value of calcium therapy in allergic conditions is debatable and has been the subject of much attention over many years, and on this subject Dr. R. A. Cooke, one of the leading American authorities on allergy, writes: "First the blood calcium was said to be low in allergy, and when this was disproved it was then claimed that the amount of ionized calcium was too low. When this was not verified the idea was put forth that the ratio of calcium to other bases as potassium and sodium was abnormal. Actually there is no evidence that there is any disturbed calcium metabolism or that calcium therapy by mouth or vein has any effect on any allergic reaction" (R. A. Cooke, *Allergy in Theory and Practice*, 1947, p. 548, London). Dr. L. Tuft, another leading American authority on allergy, writes: "In spite of the absence of adequate laboratory or even clinical proof of its efficacy in allergic conditions, calcium therapy still is employed extensively in treatment of such allergic conditions as urticaria, angioneurotic oedema, and serum disease. Its value is doubtful" (L. Tuft, *Clinical Allergy*, 1949, p. 124, London). My personal experiences with intravenous calcium in acute allergic episodes of the angioneurotic oedema type have not been in any way so consistently or dramatically beneficial as is suggested by the literature to which Dr. Woolman draws our attention. I regret I cannot support Dr. Woolman. May I also comment on—"Continental doctors are more calcium-minded than British doctors"? This is certainly not my impression from recent visits to the Continent, although my experience is, of necessity, limited to individuals especially interested in allergic conditions, individuals, I may add, of international fame.

Correction.—The name of Dr. N. W. Rawlings, who has been promoted to Commander (Brother) in the Venerable Order of the Hospital of St. John of Jerusalem, was omitted from the list of promotions in, and appointments to, the Order published in the *Journal* (January 19, p. 160).

HEALTH SERVICE CHARGES

1s. ON PRESCRIPTIONS

The Chancellor of the Exchequer, Mr. R. A. Butler, announced in Parliament on January 29 that the following changes in the Health Service would be introduced:

- (1) A charge of 1s. on prescriptions.
- (2) A charge for some appliances such as surgical belts and boots, hearing-aids, and wigs when these are supplied through the hospital service to out-patients.
- (3) Hospital amenity beds will cost more.
- (4) The powers of local authorities to charge for the use of day nurseries will be extended.
- (5) In the dental service £1 will be charged, or the full cost if less, for all treatment except dentures, where a charge is already made. This new charge will not apply to children or to expectant and nursing mothers.

The Chancellor stated that in cases of hardship help would be given in meeting the charges.

Estimated Revenue

The shilling on prescriptions in general practice will bring in some £12m. in a full year, and on hospital out-patient prescriptions about £500,000. Charges to hospital out-patients for appliances are expected to save a little less than £500,000, and increased charges for day nurseries just under £250,000. The amenity bed charges will bring in some £200,000, and the dental charges about £7½m.

Emergency Meeting

The General Medical Services Committee held an emergency meeting on February 7 to discuss the new charges. Its views will be reported here next week.

THE NEW CHARGES

The charge of 1s. on prescriptions is to be made under the National Health Service (Amendment) Act, 1949.

The other charges are to be made under a National Health Service Bill introduced by the Minister of Health on February 1. Under this Bill 1s. will be charged for drugs and medicines supplied through hospital out-patient departments. A charge up to half the cost will also be made for surgical boots and shoes, surgical abdominal supports (not hernia belts), elastic hosiery, wigs, and hearing-aids and batteries. It is proposed to charge the full cost of repairs undertaken through the Health Service. Exempted from charges are children under 16 or in full-time attendance at school, persons or their dependants receiving national assistance, and war pensioners in respect of an accepted disability.

The full cost of dental treatment (apart from dentures) will be charged up to £1. Excluded are schoolchildren, expectant and nursing mothers, and hospital patients. Where both treatment and dentures are provided the total cost to the patient must not exceed the present maximum of £4 5s. The Bill empowers local health authorities to charge for the use of day nurseries in accordance with the person's means. (At present they may charge only for meals and articles provided.)

The charge for amenity beds in hospitals is to be doubled. The new charges will be half the cost up to 12s. a day for a single room and a quarter of the cost up to 6s. for a bed in a small ward.

Penalties for Evasion

For deliberate evasion of charges a fine not exceeding £100 may be imposed, or imprisonment for three months, or both.

DETAILS OF GENERAL PRACTICE SCHEME

Dispensing doctors and chemists are the people that the scheme makes responsible for collecting the charges from the patients.

One shilling is to be charged in respect of an item or items ordered on any one Form E.C.10 or supplied by a dispensing doctor on any one occasion. The definition of "any one occasion" is as

ADJUDICATION EXPECTED IN MARCH

As announced last week, respective counsel of both sides met Mr. Justice Danckwerts on January 30 to discuss the procedure for the hearing of the general practitioners' remuneration claim. As a result of this meeting it is expected that the actual hearing will take place during March. Further details will be announced as soon as possible. Meanwhile frequent meetings are being held with counsel and the team of advisers who are completing the case to be submitted to the judge.

follows: drugs and appliances will be deemed to be supplied on one occasion, even though supplied at different times, if they are supplied at or following a visit or attendance and before a succeeding visit or attendance takes place. A repeat supply is not deemed to take place on the same occasion as the original supply even though there has been no intervening visit or attendance.

Doctors are asked not to increase the quantities normally ordered on any one occasion.

The following charges will be made for elastic hosiery; 5s. each for elastic anklets, knee-caps, leggings, and thigh pieces; and 10s. each for elastic knee-leggings, stockings, thigh knee-caps, knee stockings, thigh leggings, and thigh stockings.

Dispensing doctors are required to collect and retain the charges. Their remuneration will be adjusted in accordance with the following scheme.

Doctors Paid on Drug Tariff

Adjustment of Executive Council Payments.—A deduction of 1s. will be made in respect of each form submitted for pricing which does not contain an order for elastic hosiery, and an appropriate deduction will be made (5s. or 10s.) in respect of each item of elastic hosiery supplied.

Payment on Account.—This will be calculated on the same basis as at present but will be reduced by 1s. in respect of each form declared when the prescriptions are submitted for pricing. This reduction will be adjusted when the pricing office certifies the correct amount after making additional deductions in respect of elastic hosiery.

Dispensing Doctors Paid by Capitation Fee

An appropriate deduction will be made (5s. or 10s.) from the doctor's payments for dispensing each item of elastic hosiery. A prescription to claim payment for elastic hosiery should be written on a separate form. A deduction of 1s. will be made for each prescription for any other item or items on the special list supplied on any one occasion for a particular patient (for definition of "any one occasion" see above). Such items when given to a patient on one occasion should, for purposes of payment, be written on one prescription form.

Refund Claims by Patients

Patients being treated for a war disability accepted by the Ministry of Pensions may claim a refund for drugs or appliances prescribed in the treatment. Persons or their dependants receiving assistance grants from the National Assistance Board may apply for a refund if there is hardship.

People claiming these refunds should be given a receipt on Form E.C.57, supplies of which will be sent to dispensing doctors and chemists.

Other people may claim for a refund on grounds of hardship through the National Assistance Board, but will be required to disclose their means.

SOME COMMENTS

The Amendment Act

The Act enabling the Minister of Health to make charges in the Health Service is the National Health Service (Amendment) Act, 1949, which became law on December 16, 1949, when Mr. Aneurin Bevan was Minister of Health. The relevant words in it (Section 16) are as follows:

Regulations may provide for the making and recovery, in such manner as may be prescribed, of such charges, in respect of such pharmaceutical services, as may be prescribed, and may provide for the remission or repayment of the charges in the case of such persons as may be prescribed.

The First Announcement

It was on October 24, 1949, that Mr. Attlee, then Prime Minister, announced his Government's proposal to make a

charge of not more than 1s. for each prescription under the National Health Service. He said that the purpose was to reduce excessive and in some cases unnecessary resort to doctors and chemists. The resultant saving would contribute about £10m., although this was not the primary purpose of the charge. Old-age pensioners would not have to pay it. The clause giving effect to this proposal was inserted into the N.H.S. (Amendment) Bill in the House of Lords on November 17, 1949.

Views of Annual Conference

Meanwhile the Annual Conference of Local Medical Committees had met on October 27, 1949. It carried unanimously the resolution:

This Conference places on record its opinion that under no circumstances whatever shall the doctor be required to be an agent to collect a Government charge on prescriptions.

Views of Representative Body

At the last Annual Representative Meeting held in June, 1951 (*Supplement*, June 23, 1951, p. 272), a motion proposing a token payment was lost. It read as follows:

That, in the interest of national economy and in order to minimize both abuse of the Service and of general practitioners' time, this meeting favours the imposition of a token payment for every prescription or similar service rendered by a practitioner, this confirming the decision previously made by H.M. Government.

Speakers favouring the token payment argued that it would improve the doctor-patient relationship and deter excessive demands for drugs. Speakers against the motion emphasized that there should be no financial barrier between the patient and all necessary treatment, that the suggestion was impracticable, and that it was impolitic.

Isle of Man Experience

There is already a 6d. charge on prescriptions in the Isle of Man Health Service. It has been working for just over a year, after an initial dispute between the Tynwald (the Manx Parliament) and the doctors and chemists.

Charge and Counter-charge

In a statement on the new National Health Service Bill issued by Mr. Aneurin Bevan on February 1 he said: "If this is carried into law it means that the free Health Service is dead. The present charges on dentures and spectacles were to end in 1954. This Bill makes them permanent. . . . The temporary financial crisis has been eagerly seized upon as an excuse to destroy the National Health Service."

Speaking in London on February 2, Mr. David Gammans, Assistant Postmaster-General, said (*The Times*, February 4): "Mr. Bevan wants us to believe that a country which spends £778m. on tobacco, £488m. on beer, £650m. on gambling, and £107m. on going to the cinema every year cannot afford this charge of £10m. to put the National Health Service on a sound basis."

See leading article in Journal at p. 312.

YOUNG DOCTORS HIT

NEW HIRE-PURCHASE ARRANGEMENTS

The Government has decreed that for any article bought by hire-purchase a deposit of at least one-third of the price must be paid, and payment must be complete within 18 months. This scheme will seriously affect young doctors starting in practice.

A car is essential for them, but some doctors have already reported to B.M.A. Headquarters that they cannot find the money to put down the deposit of one-third; nor would they be able to pay off within 18 months. The position is particularly serious, because the doctor must take up a car as soon as it becomes available; otherwise it passes to the next man on the list who can pay for it.

The B.M.A. is bringing the matter before the Treasury.

HEALTH CENTRE FOR NEW TOWN

PIONEER DEVELOPMENT IN ESSEX

The new town of Harlow, which is rising out of the void in the flat country of Essex, has 664 dwellings completed, 978 in course of erection, and a further 462 out to contract. It has also 11 factory units occupied, 12 in course of erection, and 9 projected, and 25 shops are under construction and due to be completed within a few weeks. A temporary primary school has been opened, two club-rooms are available, and a cinema is threatened for the autumn. The town is ringed and intersected with 14 miles of roads, and is planned to be self-contained, not to be another dormitory suburb of London, 20 miles away.

Amid all this hustle of development a health centre has been established and is busily at work. It is a finished job, including the two cheerful waiting-rooms, the four consulting- and examination-rooms, and the accommodation for the local authority clinics, down to the kitchenette and the pram shed. The centre had been already in service for a week when it was officially opened on January 28 by Mr. A. E. Marples, Parliamentary Secretary deputizing for the Minister of Housing and Local Government. The company present included Sir Ernest Rock Carling, a trustee of the Nuffield Provincial Hospitals Trust, which has made this venture possible by means of a grant, Dr. Stephen Taylor, a member of the Harlow Development Corporation, who has been the moving spirit in the whole affair, and many members of Essex local authorities and of the medical profession in the area.

General Practitioners and County Clinics

This health centre claims to be the first in which general practitioners and county clinics are working under the same roof, and such a pioneer effort in the middle of what appears to be at first glance a vast estate given over entirely to builders and contractors, a town in the making, has been possible only as the result of specially good fortune. No permanent premises for health centre purposes could be provided by the Essex County Council until the population of the new town reached 10,000, and it is at present some 2,000. The Harlow Development Corporation, however, felt that the forelock of time should be vigorously pulled, and that health services should function from the very

beginning and be grouped to avoid so far as possible the growth of individual practices attached to houses. This meant a compromise in the acceptance of a minimum of space and of expenditure and the rendering of a maximum of service and co-operation. A pair of semi-detached "lower-income-group" houses (three-bedrooms) were made into one unit to serve as a centre for group practice and local authority clinic services.

The county council and the local executive council gave assistance, the former by leasing from the Development Corporation part of the accommodation for five years for their own clinics, and the latter by agreeing to the direct

letting by the Corporation of accommodation for medical and dental practice. The financial problem, however, had still to be solved, for the Government subsidy on the two houses would be forfeited, and the cost of conversion, adaptation, and furnishing had to be faced. At this juncture the Nuffield Provincial Hospitals Trust stepped in and made a grant of £2,450 towards the cost of the building, which, including the equipment, is expected to be about £6,500.

Economical Use of Space

The accommodation at the centre is small, even inconveniently small. Each of the consulting-rooms measures only about 10 ft. by 10 ft., but built-in cabinets and other devices ensure the use of every inch of space, and the usual facilities for general-practitioner examination are available. Adjoining each consulting-room is a smaller examining-

room containing couch and lamp. There are four sets of consulting- and examination-rooms. One of them is fitted up as a dental surgery, with a subsidiary surgery containing x-ray apparatus, and beyond this a dental mechanics' room, and a dark-room. Only two of the three doctors' consulting-rooms are so far furnished, and only one doctor at present works at the centre. As the population grows there will be a second and a third doctor. The appointments are the responsibility of the local executive council.

There are two waiting-rooms, one on each floor, curtained and carpeted to give a homelike appearance, with chairs of different sizes, small for children, and capacious for portly adults, and an electrical indicator which informs the waiting-patient that the doctor is disengaged. Other rooms in the building are fitted for the purpose of a maternity and child welfare clinic, a clinic for minor ailments, and the school medical service. The nearest general

Reprinted from *The Nuffield Provincial Hospitals Trust Report*, 1948-51, p. 46.
Architects: E. Maxwell Fry and Jane Drew.

hospitals are at Epping and Bishop's Stortford, but there is not any special link with the centre.

Use It Well

It is considered that the centre will be capable of serving ultimately a population of 10,000. After the five years' lease has expired it may be necessary to put up a special-purpose building instead of using adapted private houses. The doctors, we understand, will each pay a rent of about £275 a year for their premises, with the facilities. The day-to-day running of the centre is to be done by a small house committee, to consist of the doctors and the dentist, with representatives of the county council and the Development Corporation.

The centre is named Haygarth House, and a portrait of John Haygarth, M.D., of Chester, hangs in the waiting-hall. There appears to be no local link with Haygarth; the name was chosen because it suggested a good example of the old-time family physician, who was also an epidemiologist.

At a luncheon following the opening the Minister congratulated all concerned, especially the woman architect (Jane Drew) who was responsible for much of the skilful and pleasing design. A tablet was unveiled on which it was stated that Haygarth House is a place of healing and health planned for the people of Harlow. It placed on record an appreciation of the timely help of the Nuffield Trust, and concluded with the exhortation: "This is your health centre: use it well."

RADIOLOGY AND PATHOLOGY

ACCESS FOR GENERAL PRACTITIONERS

It has often been contended that general practitioners should have easy access to x-ray and pathology facilities, and especially that the contact should be direct with the department—the "open door" policy. Critics have contended that there might be far too many requests, so that the departments would be overloaded with work, or that a considerable number of the requests would be ill-informed and the better for being weeded out early on. Some general practitioners have direct access to such departments, but many others have not. The latter are prevented from having it partly, perhaps mainly, because the departments are already full of work and feel that their services might be abused if they opened their doors to the family doctor.

In order to obtain some evidence on this state of affairs from pathologists and radiologists, an inquiry has been carried out among 10 of them by the General Practice Review Committee of the B.M.A. This Committee is inquiring into all aspects of the conditions in general practice by means of questionnaires and personal interviews. A short account of the evidence given by the pathologists and radiologists is set out below.

Practically No Abuse

The outstanding point they all make is that there is practically no abuse of their services. As one pathologist puts it: "In general we do not find that general practitioners abuse any facilities that are available to them." Another says, "Occasionally an examination may be requested that seems to us to be pointless, but a short talk on the telephone usually clears up the trouble, and we are either convinced that this is a reasonable request and deal with it or we convince the practitioner that it is not reasonable and throw the specimen away." "With the exception of pregnancy diagnosis," another pathologist states, none of the requests are frivolous, but he does think that requests from one or two practitioners are sometimes unnecessary. He links this with the amount of private practice they have, and he mentions that one doctor uses the laboratory "to impress his private patients with the speed with which he can get investigations done."

A radiologist, who states that frank abuse of his department is rare, points out that general practitioners recognize the use of it as a privilege which they would be loath to lose. He finds that tactful handling of wasteful requests is essential, and he refuses to do certain kinds of unnecessary routine work. Two radiologists who refer to abuse of their services say that more of it comes from inside the hospital than from outside.

Useful Relationship

Most of these consultants agree that while the open-door policy brings more work it also brings a useful and friendly relationship between themselves and the general practitioners. But one of them doubts whether in fact the work is increased.

A radiologist, agreeing that direct contact improves the relationship between hospital and general practitioner, adds that the open-door policy "should be confined to the general-practitioner hospitals" because of the amount of work in the radiological departments. Another radiologist draws a distinction between private and N.H.S. patients. He thinks that in private practice direct contact between general practitioner and radiologist is in the best interests of the patient and of economy. But for N.H.S. patients he concludes that a closed hospital department for x-ray examinations is in the best interests of patients: "Being N.H.S. cases, there tends to be less direct consultation with the radiologist, and so it is better that patients should be referred from the out-patient department for their x-ray examinations."

While welcoming improved relations with the general practitioners in their areas, several consultants regret that there is too little personal consultation with them.

ACTION OF G.M.S. COMMITTEE

During recent months the General Medical Services Committee has made repeated representations to the Ministry of Health to increase pathological and x-ray facilities direct for the general practitioner. The Ministry's response is sympathetic. It states that in about four-fifths of hospital centres there is at least one hospital which provides these direct facilities. Senior administrative medical officers in the remaining areas have been asked to remedy the position as soon as practicable.

Where lack of these facilities is causing difficulties local medical committees have been asked to take the matter up with the local hospital management committee or board of governors. If these requests fail, the G.M.S. Committee will take up individual cases with the Ministry of Health.

COST OF PRESCRIBING

LOCAL VARIATIONS

The latest information from the Joint Pricing Committee for England shows that the average total cost per person of prescriptions varies a good deal between one locality and another. In October, 1950, the average cost per person for England as a whole was 16.79d., in November it was 18.57d., and in December it was 17.64d.

Of the executive councils, Chester headed the list in each of these three months with an average cost of 25.65d. in the first, 29.43d. in the second, and 28.12d. in the third. In each of the three months Huntingdonshire came bottom of the list with an average cost of 10.33d. in the first, 11.21d. in the second, and 10.90d. in the third.

Wigan came second in the list after Chester in each of the three months, and Bournemouth came third in October and November, Southport being third in December, with Bournemouth fourth. Above Huntingdonshire at the bottom of the list came Shropshire in each of the three months, and Northamptonshire came just above that.

See leading article at page 312 of the Journal.

EXCHANGE VISITS WITH CANADA AND U.S.A.

The scheme initiated last year, with the approval of the Bank of England, for exchange visits between members of the American, British, and Canadian Medical Associations will be continued this year.

Exchanges with Canada: Two doctors from Britain may visit Canada in exchange for two doctors from Canada. Each doctor from Britain will be required to make all his own travel arrangements and to deposit up to £200 with the B.M.A. in London. On arrival in Canada he will be met by a representative of the Canadian Medical Association, who will present him with the equivalent in Canadian dollars. Similarly, each Canadian doctor on arrival in Britain will be met by a representative of the B.M.A., who will present him with the sum deposited in sterling.

Exchanges with the U.S.A.: Three doctors from Britain may visit the U.S.A. in exchange for three doctors from the U.S.A. Each doctor from Britain will be required to make all his own travel arrangements and to deposit up to £200 with the B.M.A. in London. On arrival in the U.S.A. he will be met by a representative of the Medical Society of the State of New York, who will present him with the equivalent in U.S. dollars. Similarly, each U.S. doctor on arrival in Britain will be met by a representative of the B.M.A., who will present him with the sum deposited in sterling.

The duration of the visits is left to the discretion of the doctors concerned. The American, British, and Canadian Medical Associations cannot accept any responsibility for a doctor who allows his visit to outlast the money placed at his disposal.

Applications are invited from members of the B.M.A. to take part in such exchanges in 1952. Each applicant must state the object of his visit. Medical practitioners in all branches of the profession, including general practice and public health, are eligible. Applicants should also give approximate dates of the visit desired. (Successful applicants will in due course be required to give exact dates and details of travel.) Applications must be received by the Secretary of the B.M.A. by March 1.

HOSPITAL ALLOCATIONS CUT

The Ministry of Health has told hospitals that they may now spend only 80% of the ordinary capital allocations to them. The previous figure was 85%. Shortage of steel is responsible. In addition investment from a central reserve will not be found for any large schemes unless they have already been awarded starting dates.

APPOINTMENT OF OPHTHALMIC MEDICAL PRACTITIONERS ON OPHTHALMIC SERVICES COMMITTEES

The B.M.A. and the Faculty of Ophthalmologists are at present seeking nominations in connexion with the appointment of ophthalmic medical practitioner members to ophthalmic services committees for the 1952-3 session. A communication has been addressed to every ophthalmic medical practitioner on the Central Ophthalmic List on this matter, but the response so far has been disappointing. There are nearly 400 vacancies to fill, and the co-operation of every ophthalmic medical practitioner willing and able to serve on these committees is sought.

Ophthalmic medical practitioners are therefore asked to nominate any of their colleagues who are willing to serve on the local committee as soon as possible. Additional

copies of the appropriate nomination form can be obtained from B.M.A. House, Tavistock Square, London, W.C.1, and should be completed by the nominator and the candidate and returned to the Secretary of the B.M.A. *not later than Friday, February 15.*

Heard at Headquarters

Common Sense on Social Problems

The Council at its long meeting on January 23 was pre-occupied with many matters internal to the Association, especially the vexed question of economy, and therefore two pieces of work of a kind which the Association does superlatively well slipped through without appreciative comment. One of these was a memorandum of evidence which a committee under Dr. Dain has drawn up for submission to the Royal Commission on Marriage and Divorce. The proposals put forward were marked by a sound common sense, although one never knows what prejudices may be encountered in such a field. The other piece of work, by a committee under Dr. Doris Odium, was the evidence which it is proposed to furnish to the Ministry of Education committee on maladjusted children. Here proposals were put forward which may have an important bearing on the future of child guidance clinics and indeed on child psychiatry generally. The evidence of these committees will be reported when it is made public.

Surgeon Prime Minister

London during recent weeks has had the opportunity of hearing several speeches by Sir Godfrey Huggins, Prime Minister of Southern Rhodesia (he has been Prime Minister for nearly 19 years), who is also a Fellow of the Royal College of Surgeons of England and manages to combine with high executive office the practice of his profession in the wide spaces of South Central Africa. Sir Godfrey Huggins's address to the Royal African and Royal Empire Societies the other day showed him to be an alert and forceful speaker. It was said some time ago that he was accustomed to devote two hours each morning to his professional work, and then to take on his daily task of Prime Minister. During recent years he has conducted at least two major operations on governors of Southern African territories. Medicine makes such claims on those who follow it that few medical men have reached high office in the State, but South Africa a generation ago offered another example in Sir Starr Jameson, who was at one time Prime Minister at the Cape. Incidentally, both Jameson and Sir Godfrey Huggins qualified in London, and for health reasons settled in South Africa and took up practice there.

National Presidents

One of the consequences of holding the Annual Meetings of the Association only in certain large centres—a course which is now being proposed—is that the President of the Association, instead of being elected on the nomination of the local Branch, would be elected on a national basis. The method which has obtained up to now, of nomination by the Branch acting as host to the meeting, has resulted on many occasions in bringing to the office of President a man of national eminence in medicine. But with meetings held mostly in the provinces it has meant that many men in London whom it would have been desirable to have as Presidents have necessarily been passed over. It has been necessary often to explain to outsiders why it is that some eminent figure in medicine has never been President, and, occasionally, why someone who was not known beyond his own locality has been chosen for that office.

British Medical Association and Irish Medical Association

JOINT ANNUAL MEETING—DUBLIN, JULY 3-11, 1952

President-Elect: P. T. O'FARRELL, M.D., F.R.C.P.I., D.T.M., D.P.H., Dublin

PROVISIONAL PROGRAMME

The 120th Annual Meeting of the British Medical Association will be held in Dublin from Thursday, July 3, to Friday, July 11, 1952, as a joint meeting with the Irish Medical Association.

The first part of the Meeting—the Annual Representative Meeting—will be held in the Round Room, Mansion House, Dublin, starting at 10 a.m. on Thursday, July 3, and concluding on Monday, July 7.

The Overseas Luncheon and Representatives' and Ladies' Dinners will take place on Thursday, July 3; and there will be all-day excursions for Representatives and their Ladies on Sunday, July 6.

The adjourned Annual General Meeting and President's Address will take place at Trinity College on the evening of Monday, July 7, and will be followed by the President's Reception.

At an early stage of the second part of the Meeting—the Annual Meeting proper—there will be two Religious Services, Protestant and Catholic, held concurrently at 9 a.m. on Tuesday, July 8, preceding the opening Plenary Scientific Session, to be held in the Round Room, Mansion House.

The holding of three Plenary Scientific Sessions on the mornings of July 8, 9, and 10, in addition to the meetings of the Scientific Sections, is an innovation which it is hoped will prove of interest to the majority of members. These Plenary Sessions will be addressed by a number of experts and then opened for questions or general discussion. The subjects chosen are: "Death in Early Adult Life," "The Relief of Pain," and "Body Fluids and Water Balance."

In addition to the Plenary Sessions there will be 14 Scientific Sections, meeting in the afternoons of Wednesday and Thursday, July 9 and 10, and all day on Friday, July 11, at Trinity College and University College, Dublin. These Sections will be:

Medicine	(Two sessions) July 10 (p.m.), 11 (a.m.)
Surgery .. .	(Two sessions) July 9 (p.m.), 10 (p.m.)
Obstetrics and Gynaecology ..	(Two sessions) July 11 (a.m. and p.m.)
Anaesthetics .. .	(One session) Date not settled
Cardiology .. .	" "
Child Health .. .	" "
Ophthalmology .. .	" "
Orthopaedics .. .	" "
Oto-rhino-laryngology .. .	" "
Pathology .. .	" "
Psychiatry .. .	" "
Radiology .. .	" "
Social Medicine and Occupational Health .. .	" "
Tropical Medicine .. .	" "

Individual programmes for these Sections will be published in a later issue of the *Journal*.

The Annual Dinner of the Association will be held on Thursday, July 10, and it is hoped that the Popular Lecture will be given on the evening of Friday, July 11.

Among the many social functions to be arranged it is hoped to hold a Reception for Overseas Delegates on the evening of Tuesday, July 8; a State Reception on the evening of Wednesday, July 9; a Garden Party at Trinity College

on the afternoon of Thursday, July 10; and a dance at the Royal College of Surgeons in Ireland on Friday, July 11.

It is proposed to hold the Secretaries' Conference in Dublin on the afternoon of Tuesday, July 8, and the Overseas Conference on the afternoon of Wednesday, July 9.

The Reception Room for registration in University College, Earlsfort Terrace, will be opened on Monday, July 7, at 9 a.m. The Ladies' Club will be situated at Newman House, St. Stephen's Green, and will be open throughout the Meeting.

The Annual Exhibition of Surgical Appliances, Foods, Drugs, and Books will be housed in University College, Dublin. The official opening will take place on Monday, July 7, at 9 a.m., and the Exhibition will remain open on July 8, 9, 10, and 11, from 9 a.m. to 6 p.m.

It is hoped also to hold a small Scientific Exhibition in University College, Dublin (in place of the Pathological Museum); particulars of this will be given later.

ACCOMMODATION AND TRANSPORT

Dublin is a capital city of great charm and beauty which cannot fail to provide something of interest to every visitor. It is rich in history, architecture, variety of scenery, and variety of entertainment.

There is adequate hotel accommodation in the city itself, but for those who prefer it there are, within easy travelling distance, a number of seaside and country areas where pleasant accommodation can be found.

An abridged list of hotels, together with approximate costs, is given below, and members are asked to make their reservations direct with the hotel concerned, and to state that they are attending the B.M.A. and I.M.A. Meeting. The Irish Tourist Association, of 14, Upper O'Connell Street, Dublin, is available for information and advice to any members who would like further particulars regarding accommodation.

There are a number of alternative routes open to members visiting Dublin, but traffic on *all* these routes during the summer months is very heavy. For the comfort and convenience of members, therefore, the Association has approached the transport companies with a view to securing reservations on trains and planes. These reservations can be made, however, only if the companies receive in good time an indication of the number of passengers likely to travel by the various routes.

The Shirley James' Travel Service, Ltd., of Tavistock House South, Tavistock Square, London, W.C.1, the official Travel Agency for B.M.A. House, has been asked to handle these travel inquiries, and members are invited to communicate with this Agency *as soon as possible*, stating the route selected, the proposed date of travel to and from Dublin, and the number of passengers. Briefly, the alternative direct routes open to visitors to Dublin are as follows:

Air
Birmingham-Dublin
Bristol-Dublin (restricted service)
Glasgow-Dublin
Liverpool-Dublin
London-Dublin
Manchester-Dublin

Rail and Sea
Holyhead-Dun Laoghaire (Kingstown)
Liverpool-Dublin
Glasgow-Dublin (restricted service)

GENERAL INFORMATION

Passports or travel permits are necessary when visiting Ireland, but no ration cards are required. There is no Customs restriction upon taking in reasonable personal effects.

Visitors may hire motor-cars in Dublin, thus avoiding the expense and trouble attached to taking cars over. The cost of hire is approximately £12 12s. a week for self-driven cars, and chauffeur-driven cars may be hired for about 1s. 3d. a mile. Those wishing to take over their own cars are advised to get in touch with the A.A. or R.A.C. as early as possible, as facilities are restricted.

FIRST LIST OF HOTEL ACCOMMODATION

Name and Address of Hotel	No. of Rooms	Bed and Breakfast per Day From	Full Board per Day From (Minimum 3 Days)

TIME-TABLE OF MEETING

Thursday, July 3

- 9.00 a.m.—A.R.M. Inquiry Office opens at Mansion House, Dawson Street.
 9.30 a.m.—Ladies' Club opens at Newman House, St. Stephen's Green, for registration of Ladies and for tours.
 10.00 a.m.—Annual Representative Meeting opens at Mansion House, Dawson Street.
 11.00 a.m.—Welcome by Lord Mayor of Dublin to A.R.M.
 1.00 p.m.—Overseas Luncheon, Royal Hibernian Hotel, Dawson Street.
 2.30 p.m.—Excursions for Ladies.
 7.30 p.m.—Dinner for Representatives at Gresham Hotel, O'Connell Street.
 7.30 p.m.—Dinner for Representatives' Ladies at Metropole Restaurant, O'Connell Street.
 The dinners will be followed by a Reception and Dance at Gresham Hotel.

Friday, July 4

- 9.00 a.m.—A.R.M. Inquiry Office open, Mansion House.
 9.30 a.m.—Ladies' Club open, Newman House.
 9.30 a.m.—A.R.M., Mansion House.
 2.30 p.m.—Excursions for Ladies.
 7.30 p.m.—Abbey Theatre or evening excursions.
 7.30 p.m.—Edinburgh Graduates' Dinner.

Saturday, July 5

- 9.00 a.m.—Council Meeting, Council Chamber, Royal College of Physicians.
 9.00 a.m.—A.R.M. Inquiry Office open, Mansion House.
 9.30 a.m.—Ladies' Club open, Newman House.
 10.00 a.m.—A.R.M., Mansion House.
 2.30 p.m.—Excursions for Ladies.
 7.30 p.m.—Glasgow Graduates' Dinner.
 7.30 p.m.—Welsh Dinner.
 7.30 p.m.—Abbey Theatre or evening excursions.

Sunday, July 6

- a.m.—Long excursions by coach.
 p.m.—Short excursions by coach.
 Evening Concert.

Monday, July 7

- 9.00 a.m.—A.R.M. Inquiry Office open, Mansion House.
 9.00 a.m.—Opening of Exhibition by President-Elect, University College, Earlsfort Terrace.
 9.00 a.m.—Reception Room opens at University College, Earlsfort Terrace, for registration.
 9.30 a.m.—A.R.M., Mansion House.
 10.00 a.m.—Annual Meeting, Irish Medical Association, Physics Theatre, University College, Dublin.
 12.30 p.m. (or as soon thereafter as the business of the A.R.M. is concluded).—Annual General Meeting, Mansion House.
 Council Meeting (at conclusion of A.R.M.).
 8.30 p.m.—Adjourned Annual General Meeting and President's Address, Trinity College.
 9.30 p.m.—President's Reception, Trinity College.

Tuesday, July 8

- 9.00 a.m.—Roman Catholic Service, Pro-Cathedral.
 9.00 a.m.—Protestant Service, Christ Church Cathedral.
 9.00 a.m.—Reception Room and Exhibition open, University College.
 9.30 a.m.—Ladies' Club open, Newman House.
 10.45 a.m.—Scientific Plenary Session, Mansion House.
 2.30 p.m.—Secretaries' Conference, Royal College of Physicians.
 8.00 p.m.—Reception for Overseas and Foreign Representatives and Delegates.

Wednesday, July 9

- 8.30 a.m.—Annual Medical Missionary Breakfast.
 9.00 a.m.—Reception Room and Exhibition open, University College.
 9.30 a.m.—Ladies' Club open, Newman House.
 10.00 a.m.—Scientific Plenary Session, Mansion House.
 10.00 a.m.—Notts Ladies' Challenge Cup Golf Competition.
 10.00 a.m.—Leinster and Childe Cup Golf Competition.
 10.00 a.m.—Excursion and tours.
 12 noon.—Visit to St. James's Brewery.
 2.30 p.m.—Overseas Conference, Royal College of Surgeons.
 2.30 p.m.—Scientific Sections, University College and Trinity College.
 2.30 p.m.—Short tours.
 8.00 p.m.—State Reception.

Thursday, July 10

- 9.00 a.m.—Reception Room and Exhibition open, University College.
 9.30 a.m.—Ladies' Club open, Newman House.
 10.00 a.m.—Scientific Plenary Session, Mansion House.
 10.00 a.m.—Treasurer's Cup Golf Competition.
 10.00 a.m.—Excursions and tours.
 12 noon.—Visit to St. James's Brewery.
 2.30 p.m.—Short tours.
 2.30 p.m.—Scientific Sections, University College and Trinity College.
 4.00 p.m.—Garden Party at Trinity College.
 7.30 p.m.—Annual Dinner.

Friday, July 11

- 9.00 a.m.—Reception Room and Exhibition open, University College.
 9.30 a.m.—Ladies' Club open.
 10.00 a.m.—Scientific Sections, University College and Trinity College.
 10.00 a.m.—Excursions and tours.
 2.30 p.m.—Scientific Sections, University College and Trinity College.
 8.00 p.m.—Popular Lecture.
 9.30 p.m.—Dance in aid of R.M.B.F. Society of Ireland at Royal College of Surgeons in Ireland.

DOCTORS' HOBBIES

EXHIBITION AT ANNUAL MEETING

It is proposed, if sufficient response from intending exhibitors is received, to hold an exhibition of doctors' hobbies at this year's meeting of the B.M.A. and I.M.A. in Dublin.

The exhibition will be of paintings, drawings, literature, practical handwork, and collections of various objects from stamps to silver and glassware. Will those willing to ensure the success of this venture please communicate at once, giving particulars of proposed exhibit, with Dr. F. S. Bourke, 14, Fitzwilliam Square, Dublin? Any articles loaned for exhibition will be covered by insurance.

Correspondence

Sale of Goodwill

SIR,—Scarcely a week passes without one or more letters appearing in your columns complaining of difficulties created by that part of the National Health Act which prohibits the sale of practices or partnerships. Hundreds of recently qualified doctors are unable to get into practices; older doctors are unable to leave the busy urban practices and finish their time in quiet country areas; retiring doctors find that the compensation offered is hopelessly inadequate with present-day costs; widows are afraid to sell their houses to incoming doctors, and so on, *ad infinitum*.

It would be interesting to know exactly *who* has benefited by these oppressive and cumbersome clauses in the Act. They have certainly done no good to the patients, and it is clear that they are nothing but an incubus to the profession. However, Socialist principles, as laid down by the late unlamented Minister of Health, were satisfied.

I suggest that, now that Socialism has been rejected by the country, these clauses should be wiped out of the Act, and the profession should regain the right to sell and buy "goodwill." The country would save the £66m. and interest payments thereon, and the *Journal* would soon be full of columns of practices and partnerships for sale. But what about the £8m. or so of "compensation" already paid to certain doctors? This could be repayable to the Ministry on subsequent sale of the practice or, better still, wiped out as one of the losses caused by Socialist mismanagement—on a par with the groundnuts.—I am, etc.,

Coventry.

D. MURRAY BLADON.

Trainee Assistant Scheme

SIR,—I have been in communication with many trainee assistants, past and present. From these statements, and very little from my own personal experience, I have come to the following opinion. In theory it is an excellent scheme, but in practice it is merely feather-bedding many of those fortunate practitioners who have been allowed to take on a trainee assistant.

I am convinced the scheme should be either withdrawn and the training brought into the medical curriculum, and thus save a small sum of money for the country, or else there should be laid down (1) definite facts about what the trainee should be taught, and (2) what is considered to be the minimum off-duty for the young doctors undergoing initial training in the ways of practice (it must be stressed at this point that the assistant is not paid by the practitioner).

The local medical committee should be made to take a greater interest in the work that the trainee is being asked to carry out, and not merely to give the said permission to established practitioners (these doctors are themselves usually associated with the committee) and then lose complete interest in the young medical man.

I agree with Dr. R. P. Gammie (*Supplement*, January 12, p. 13), who stated that no practitioner or firm should be

allowed more than three trainees—consecutive or otherwise. Since so many of the trainees have so varied off-duty, I ask, What is considered to be the minimum off-duty of complete freedom that a trainee should expect to receive?—I am, etc.,

Evesham, Worcs.

P. J. LEWIS.

SIR,—So Dr. R. P. Gammie (*Supplement*, January 12, p. 13) feels that having had a trainee assistant for three years he should now be able to get a further grant because his latest trainee has been taken into partnership. And he goes so far as to say: "From the start my partners and I set out to facilitate the introduction of an assistant to the practice with the definite aim of offering a satisfactory trainee a practice share. . . ."

Surely this is an abuse of the trainee scheme, as it appears that an assistantship with a view would have met the requirements of this practice. So far from helping young doctors to enter practice, the trainee scheme directly hinders them because of such abuse, and its total abolition is much to be desired.—I am, etc.,

Northampton.

J. LEAHY TAYLOR.

Frequent Change of Doctor

SIR,—In the "Evidence from Birmingham" (*Supplement*, January 19, p. 18) it is stated that "the introduction of the waiting period of 14 days before people can change their doctors does not seem to have had as much deterrent effect as expected." It is my very strong impression that it has had none at all.

Those who wish to change seem to do so either because their home location is nearer to the doctor of their choice or because they have no use for their old doctor, and they are not to be put off by a stupid bit of red tape. All the procedure appears to effect is waste of time of patient and of doctor (two interviews of five minutes—about long enough for a very busy G.P. to see two patients), waste of time of the executive council's clerk and of paper and envelopes, doubling the postage, and irritation all round—and all this at a time when rigid economy is said to be of paramount importance.—I am, etc.,

Thame, Oxon.

C. H. BARBER.

Charge on Prescriptions

SIR,—I wonder if it is generally realized how the charge for prescriptions will affect the rural doctor who does his own dispensing? The actual collection of the shilling will in many cases have to be done by the doctor in person, and this unprofessional conduct will undoubtedly spoil the good relationship existing between a doctor and his patient which is vital for good medical practice.

I hope it is not too late for our legislators to think again before taking a step which will undermine the prestige of the country medical practitioner. Collection of contributions by a doctor in person was unknown in club and contract practices before the Health Service. In many cases the doctor will pay the proposed shilling himself rather than take this retrograde step to the position of the "Sixpenny Doctor" of the Victorian slum areas.—I am, etc.,

Bishop Auckland, County Durham.

L. CAMA.

Public Health Award

SIR,—Assistant medical officers will be heartened to know that at the meeting of the staff side of Whitley Committee C on January 22 (*Supplement*, February 2, p. 42) the question of the revision of the assistant-medical officers' salary award under the Industrial Court was raised.

The cost of living has increased 12% during 1951 and shows no sign of halting. It is not unreasonable to ask that the staff side will not accept an increase of less than this amount. The practitioners of preventive medicine should not receive a lower betterment factor than their colleagues in general practice, whose case is now due to go to arbitration.

I understand that 20% of the local authorities have not implemented the award of the Industrial Court to public

health medical officers. Whatever the figure, what does the Association propose to do now that its bluff of "black listing" and "important notices" has been called? My resolution in the name of the Darlington Division to the 1951 Annual Representative Meeting that "in the event of an authority having failed to implement the award of the Industrial Court in full by September 1, 1951, the matter should be referred to the Ministry of Labour" was scorned as serving no useful purpose. Events have proved that I was right and the Association wrong. The general practitioners have obtained arbitration at long last by naming a date of withdrawal from the Service if it was not granted. This indicated that they meant business.

If the office bearers do not wish the Association to be brought to derision by their failure to have the award implemented, then I suggest that the British Medical Guild be instructed forthwith to notify the Minister of Labour that a dispute exists with these authorities which have not implemented the award to date, requesting him to refer the dispute to an industrial tribunal. Unless the Association takes this action, what hope is there of a revision being accepted?—I am, etc.,

MAURICE B. GRIFFITH,
Hon. Sec., Durham County M.O. Guild.

Darlington.

"Piracy"

SIR,—I am sure that there must be many besides myself who would wish to applaud most heartily the letter from my old fellow house-man Dr. H. B. Walker (*Supplement*, January 19, p. 22). I have been hoping for some time that some abler member of the depressed class than myself would take up the cudgels in defence of the rights of private property. The profession has surely sunk to about the lowest depth when the ordinary right to dispose of one's own to the highest bidder is stigmatized as "piracy."

Deprived of the right to sell our practices to the best advantage and offered instead so-called compensation on the lowest terms, having no right to superannuation, it seems that we are expected meekly to hand over our houses on similar terms, as Dr. Walker says, to "some individual whom I do not know on the instructions of some committee whom I shall certainly despise." To read some of the letters of your correspondents it would seem that the only option to be left to us of the older generation is to be the freedom of the gas oven. *O tempora, O mores!*—I am, etc.,

Bridlington, Yorks.

C. J. GORDON TAYLOR.

Unhelpful Attitude

SIR,—I read with interest Dr. Wand's address (*Supplement*, January 12, p. 9) to the Annual Meeting of the Executive Councils Association. We all expect help and guidance from our executive council. But the following case would show how the unhelpful attitude of an executive council can cause untold misery to a doctor.

Just before July, 1948, I set up practice in unsuitable premises. I asked for the lease of a site next door from the corporation. My application was supported by the executive council. The site was advertised, and out of several applicants I was duly selected. I was hoping to have decent accommodation for my surgery early in 1949. But the executive council stepped in and asked the corporation to postpone negotiations. As a condition of support I was asked to close down my branch surgery. Needing the site desperately (the only vacant site in the neighbourhood) I agreed to that condition and closed the branch surgery. I thought that was the end of my troubles and hoped to have the house ready by the end of 1949. But months passed by and no news from the corporation.

A shock was awaiting me when I went to make inquiries. I was told I could not have the site, as the executive council had asked the corporation to build the house and let it to their nominee. The executive council confirmed it. I kept my side of the agreement by closing down my branch surgery, but the executive council did not even have the

courtesy to inform me of the change in their plans. Would they promise the tenancy of the house to me? No. I was free to apply, but they could nominate someone else.

I had to appeal to the Minister against this blatant breach of faith. After several months' correspondence the executive council, owing to pressure from the Minister, agreed to reserve the house for me. I am still carrying on practice in my cramped rooms—under notice to quit—and the house is not even half-furnished.

A few weeks ago I was sent a copy of the proposed agreement for the tenancy. Rent? £6 per week. I would be responsible for rates and repairs. Thus the inclusive rental would be about £10 per week. I thought it was rather excessive. A doctor's house and surgery are an essential service and rent should be economic but reasonable.

The contract was for about £4,200. So the corporation want their capital back in 14 years. If I bought this house I would have to pay £168 as interest as against £300 as rent. How did the corporation arrive at this figure?—(1) Loss of subsidy from the Government, which they had received for ordinary houses. (2) Interest on capital. (3) Compensation for loss of site for ordinary houses. (4) Compensation for amount to be spent for conversion of this house into flats, if I moved to a health centre. Would it make any difference if I guaranteed not to move? No. If I did not move during the 15 years stipulated, would they refund me the compensation? No, it would be retained by the corporation. Clear case of profiteering? I leave it to your readers to judge.

I took up the matter with the executive council and requested them to make sure that the rent suggested was fair. I thought it was their responsibility, as they had forced me into this position. No, they cannot take any action. If I was left alone I would have had my house two years ago at a much smaller cost. I may have to wait for the house for another year and pay excessive rent, thanks to the executive council.

Birmingham is going to build several more of these doctors' houses, and perhaps other local authorities would be doing the same. A doctor selected to occupy such a house, without a list or with a small list, will have to work for a long time just to pay this rent, or let it go to someone else who can afford it. Is it right?—I am, etc.,

Birmingham.

D. R. PREM.

Middle-class Practices

SIR,—I was delighted to get a questionnaire, presumably a B.M.A. Gallup poll, asking me to put forward ideas for improving the N.H.S. It was pretty plain in 1948 that the Socialists were going to ride roughshod over the middle-class practice. As it later turned out, the "vermin" doctors like myself were going to reorientate themselves and send their late private patients off to hospital out-patients. The middle-class practice that might have been the ideal standard for the scheme was no longer a workable proposition.

The doctor who has had access to diagnostic facilities such as the laboratory, x rays, hospital beds, and consultants can no longer find too much time for these things. His surgery is choked with colds, repeat prescriptions, and certificates. And yet the problem of the middle-class patient remains. These people are not always eager to be diagnosed and treated in out-patients. As a result it is fair to say that 2,000 middle-class patients, with their expected standard of attention on the one hand, give the vermin doctor the same amount of work as the industrial-practice doctor with his 4,000 patients and the type of attention that they have always had. No recognition of this state of affairs has ever come out of the B.M.A. or the Ministry, and yet anyone who has worked in both types of practice knows it for a fact. The situation has been ignored by all except the bewildered specialist in private practice, who either goes abroad, joins the F.F.M., and/or voices protest in the agony column at the back of the *Supplement*. And

still nothing emerges except a demand for higher capitalization rate, which is not really the solution, though it is necessary.

In my opinion nobody should be paid for any patients over 3,000, and that list ought to be worth quite £3,000 a year. In this way there would be no more unemployment for the young entrants into practice, and patients would get a decent type of attention whoever they might be. Secondly, private practice would be easier if patients could elect to contract out of paying their weekly contributions, although they should still be eligible for free hospital treatment and drugs because of their support for the N.H.S. via indirect taxation. This system would help to make middle-class doctoring a more practicable proposition than it is, because the vermin doctor might be able to subsidize his list with fee-paying patients.

There was once an argument that the lists could not be limited below 4,000 in case it standardized practices enough to be the thin end of the wedge for State medicine. When one considers that some districts have an average of 1,600 patients per doctor, there does not seem so much cause for alarm, though perhaps others average 4,000. Anyway, this letter is a plea for better working conditions and a fair chance for entrants into general practice. It is the latter who will ultimately treat the patients one now has.—I am, etc.,

Hampton Hill, Middx.

I. E. D. MCLEAN.

Night Call

SIR,—As there is no redress for the G.P. except in the pleasure of letting off steam to you, I thought it might amuse you to hear the following.

My wife and I were out at a dance last week and our maid was got out of bed by the telephone at 10 p.m. The message she took was as follows, from Mrs. A's daughter at Dover: Could the doctor please call in to see her mother, since she hadn't heard from her for a fortnight?

Knowing that to neglect such a call might land me in front of a tribunal, I duly made the call. Mrs. A had a cold in the head and hadn't bothered to write; there was no need for the doctor to call really, but, since he had, could he do this, that, and the other?

Mrs. A was unable to understand why I was offended at the request of her daughter and did not propose to tell her daughter, who was rather a nervous sort of person. As the call had nothing to do with Mrs. A, I could hardly blame her and rendered what services she required. What can we do about it?—I am, etc.,

Hythe, Kent.

D. KENNEDY.

Loss of Personal Touch

SIR,—I feel it time now for the leaders of our profession to precipitate the introduction once again of the G.P.s looking after their own cases which are within their scope. There is a gross redundancy of young hospital medical officers who are too filled in their own cerebral centres with the rarities of medicine. The danger of overspecialization is all too imminent. Doctors tend to lose that personal and common-sense touch. It is the patient that matters as much as the disease. The patient requires to be educated not on the lines of intravenous pyelograms and arteriographic investigations but on the principal hygienic and prophylactic methods of keeping oneself fit. Surely bizarre electric-wave therapy and fancy massage, as given in a physiotherapy department, good as often it is, could be reduced considerably if the patient was instructed to take a hot-water bottle for his lumbago and retire to bed.

Never before in the history of this country of ours have the patients been so neurotic. X-ray investigations are needlessly desired, and the patients very often have their wish fulfilled. The time will come when doctors will be doing platelet counts for the smallest possible haemorrhage. We require the cream of medicine, and that is the

good general practitioner, to give more judgment on matters and to receive a greater entry into the care and welfare of the patient.

The public have been educated on the wrong lines to a great degree. Let them think of health rather than of illness, and by so doing we can relieve a great burden from the psychologists, who I think will agree that psychosomatic medicine has taken primary place.—I am, etc.,

Brighton.

R. K. STEEN.

Tracing Patients

SIR,—I have read the acrimonious comments from doctors who object to checking their lists. I suggest it would be politic to go with the executive councils in this as far as they want to go, and then take the councils twice as far again. How many doctors realize that they have patients on their lists who can produce medical cards, and whose medical record envelopes are in the proper place, and who may be under treatment now, but are still on the free list?

One partner in this firm recently retired, and a check of his patients alone disclosed between 60 and 70 who appear to be normal patients in every way except for the payment.

The only possible answer seems to be for the council to submit a list of his patients to each doctor once a year or thereabouts.—I am, etc.,

Shipley, Yorks.

H. S. RUSSELL.

Trade or Profession?

SIR,—I wish to protest at the way in which references are made on the B.B.C. to trade unions as applying to the medical profession. On two occasions within the last 12 months this subject has been the topic of conversation in the "Any Questions?" programme. The members taking part in that programme are presumably educated, intellectual people, yet they seem to think that, because a doctor must first have his name entered in the *Medical Register* before being allowed to practise, the medical profession is a "closed shop" and a strong trade union. Can they not see that the practice of medicine is a profession and cannot be compared with a trade?

I would be interested to know if other doctors feel irritated by these references which are broadcast to the gullible public.—I am, etc.,

Burbage, Wilts.

M. J. L. HASSALL.

Rent at Health Centres

SIR,—I do not know how correct Dr. J. F. Robinson's statement (*Supplement*, January 26, p. 32) is that G.P.s at a health centre will be charged a rental, but this is quite within the realm of probability, as anything can happen to a G.P. Most of us and our representatives have been living in a land of fantasy for many years and more so than ever since July, 1948.

The State abolished private practice and N.H.I., and established a totalitarian health service. It bought our practices (assets) at its price, holding on to the capital and paying us the interest on this which it decided should be paid, giving us no option of investing at 4.5 or 6%. It has used our surgeries and/or houses for carrying out its work without rent or allowances for phones, light, heat, paper. Our wives in, I expect, a very large number of cases have to keep the place clean, answer the phones, and answer the doors. An allowance for this is made in income tax, which means that it costs the State the tax on around £150 for these services. It also pays us a camouflaged salary which was very inadequate in 1947, when I think we went from 9s. to 15s. under N.H.I., without prejudice as to the finance of N.H.S.—all according to Spens.

Now I submit that, if the State succeeded in getting away with all this, I see no reason why it should not get away with making us pay rent for doing its and our work at a health centre and allowing us to put this down as expenses for income-tax purposes. The N.H.S. is fabulously expensive,

and this rent would reduce the cost by about £6,000,000, less our income-tax rebate. There has been a strong suggestion that it is the doctors who must reduce the cost. We are in the hands of our representatives. What do they think?—I am, etc.,

St. Osyth, Essex.

R. E. CLARKE.

Badly Set-out Form

SIR,—I am constantly being put to considerable trouble and annoyance by having Form E.C.1 (Rev.) presented or sent to me incorrectly completed by the patient. In the majority of cases they have omitted the national registration number and date of birth. This results in needless visits or letters, which are either not answered or answered weeks later. The reason for this omission lies in the fact that the form is badly set out and gives the impression that the words, "For Office Use," apply to the whole of the right-hand corner. May we please have this put to rights? I believe that this is a prevalent occurrence, and one which adds unnecessary burden to our ever-increasing administrative tasks.—I am, etc.,

Scunthorpe, Lincs.

R. H. FOXTON.

B.M.A. LIBRARY

The following books have been added to the Library:

- Adelaide Hospital Centenary Book. 1951.
Averill, L. A., and Kempf, F. C.: *Psychology Applied to Nursing*. Fourth edition. 1951.
von Baeyer, W. R.: *Die moderne psychiatrische Schockbehandlung*. 1951.
Birch's Management and Medical Treatment of Children in Tropical Countries. Ninth edition. 1951.
Brain, W. R.: *Mind, Perception, and Science*. 1951.

H.M. Forces Appointments

ROYAL NAVY

Surgeon Captain A. W. McRorie, K.H.P., has retired.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander S. B. Levy, V.R.D., has retired.

ROYAL CANADIAN NAVY

Surgeon Lieutenant-Commander R. H. Roberts to be Surgeon Commander.

ROYAL CANADIAN NAVY (RESERVE)

Surgeon Lieutenant-Commander J. D. Ross to be Surgeon Commander.

ARMY

Major-General J. M. Macfie, C.B., C.B.E., M.C., K.H.S., late R.A.M.C., has retired on retired pay.

Brigadier (Temporary Major-General) J. C. Collins, C.B.E., late R.A.M.C., to be Major-General.

Brigadier A. G. Harsant, O.B.E., K.H.S., late R.A.M.C., to be Major-General (Supernumerary).

Colonels (Temporary Brigadiers) W. L. Spencer-Cox, O.B.E., M.C., and R. J. Rosie, K.H.P., late R.A.M.C., to be Brigadiers.

Colonel G. W. B. Shaw, late R.A.M.C., having completed four years in the rank, has been retained on the Active List supernumerary to establishment.

Lieutenant-Colonels J. G. Black, E. J. Curran, and A. N. T. Menece, C.B.E., D.S.O., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J. T. Smyth, having attained the age for retirement, is retained on the Active List supernumerary to establishment.

Majors A. L. Pennefather, J. McGhie, G. F. Valentine, and E. Gareh to be Lieutenant-Colonels.

Captain P. L. G. Cole to be Major.

REGULAR ARMY RESERVE OF OFFICERS

Major-General J. A. Manifold, C.B., D.S.O., late R.A.M.C., having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

ROYAL ARMY MEDICAL CORPS

Major (Honorary Lieutenant-Colonel) R. H. Wheeler has ceased to belong to the Reserve of Officers.

Major (Honorary Lieutenant-Colonel) J. M. McF. Drew, O.B.E., has resigned his commission.

Major R. R. Simpson, J.P., has relinquished his commission, retaining the rank of Major.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Majors (acting Colonels) G. S. N. Hughes, D.S.O., W. M. Evans, O.B.E., M.C., T.D., and G. M. Frizelle, T.D., to be Colonels.

TERRITORIAL ARMY

Colonel J. B. S. Guy, C.B.E., T.D., R.A.M.C., has retired, retaining the rank of Colonel.

Colonels H. J. D. Smyth, M.C., T.D., and J. E. Rusby, M.C., T.D., R.A.M.C., having exceeded the age limit, have retired, retaining the rank of Colonel.

Lieutenant-Colonel (acting Colonel) W. E. Tucker, M.B.E., R.A.M.C., to be Colonel.

Lieutenant-Colonel W. H. Wolstenholme, O.B.E., T.D., R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel R. Mowbray has been granted the acting rank of Colonel.

Major (acting Colonel) A. G. Flemming, O.B.E., to be Lieutenant-Colonel.

Majors (acting Lieutenant-Colonels) I. C. A. D. P. Graham, T.D., N. Pycroft, M.C., and T. P. Sewell to be Lieutenant-Colonels.

Captain (acting Lieutenant-Colonel) J. F. K. Grieve to be Lieutenant-Colonel. (Substituted for the notifications in *Supplements* to the *London Gazette* dated October 9 and November 6, 1951.)

Captain (acting Lieutenant-Colonel) F. C. Rodger to be Major. Major I. C. Campbell has relinquished his commission, retaining the rank of Major.

Captain (acting Major) J. T. Mair has been granted the acting rank of Lieutenant-Colonel.

Captains J. R. S. Innes, L. R. West, W. G. Ferguson, D. K. W. Picken, and J. B. Bennett to be Majors.

Captains J. S. Binning, P. J. Duff, R. T. G. Craig, R. B. Raffle, and R. McL. Archibald to be acting Majors.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: E. A. Beet, M.R.C.S., L.R.C.P., D.T.M.&H., Specialist Physician, Nigeria; Miss E. Gemmell, M.B., Ch.B., D.T.M.&H., Lady Medical Officer, Aden; V. W. J. Hetreed, B.M., B.S., C.P.H., Specialist (Tuberculosis), Nigeria; H. M. O. Lester, O.B.E., Ph.D., M.R.C.S., L.R.C.P., Director of Medical Services, Federation of Malaya; J. P. P. Mackey, M.B., Ch.B., D.P.H., Senior Pathologist, Tanganyika; L. M. Ram, M.D., Senior Medical Officer, Social Hygiene, Singapore; G. I. M. Ross, M.B., Ch.B., F.R.C.S., Surgeon Specialist, Federation of Malaya; L. A. P. Slinger, O.B.E., M.B., B.Ch., Director of Medical Services, British Guiana; G. G. Smith, M.R.C.S., L.R.C.P., Director of Medical Services, British Honduras; R. J. Grove-White, M.B., B.Ch., M.R.C.P., D.T.M.&H., Tuberculosis Specialist, Singapore; F. S. Carter, M.B., Ch.B., Special Grade Medical Officer, Kenya; Kong Hoi Kit, M.B., F.R.C.S., Medical Officer, Hong Kong; D. Leslie, M.B., Ch.B., Medical Officer, Federation of Malaya; W. S. Lewis, M.R.C.S., L.R.C.P., Medical Officer, Sarawak; P. S. Wright, M.B., Ch.B., Gynaecological and Obstetrical Specialist, Hong Kong; J. L. R. Barlow, M.B., Medical Officer, Gold Coast; D. P. Daly, M.B., Ch.B., and R. M. Halahan, M.B., Ch.B., Medical Officers, Tanganyika; P. M. Philpott, M.B., B.S., Lady Medical Officer, Sarawak; T. A. O'Donnell, M.B., B.Ch., Medical Officer, Uganda.

- 19 Tues. B.M.A. and Royal College of Nursing Liaison Committee, 2.30 p.m.
- 20 Wed. General Medical Services Committee, special meeting, 11 a.m.
- 20 Wed. General Practice Review Committee, 11 a.m.
- 20 Wed. Association of General Practitioners with Hospital Work Committee, 2 p.m.
- 21 Thurs. Dermatologists Group Committee, 10.30 a.m.
- 21 Thurs. General Medical Services Committee, 10.30 a.m.
- 26 Tues. Central Ethical Committee, special meeting, 2 p.m.
- 27 Wed. Private Practice Committee, 2 p.m.
- 28 Thurs. Committee on Control of Medical Manpower in War, 2 p.m.
- 28 Thurs. Trainee Assistants Subcommittee, General Medical Services Committee, 2 p.m.
- 28 Thurs. Welsh Committee, special meeting (at Raven Hotel, Shrewsbury), 2.15 p.m.
- 29 Fri. Library Subcommittee, 12 noon.
- 29 Fri. Science Committee, 2 p.m.

MARCH

- 5 Wed. General-Practice Review Committee, 11 a.m.
- 10 Mon. Conference between the B.M.A., Ministry of Health, and associations of local authorities on Dual Appointments (at 1, Richmond Terrace, Whitehall, London, S.W.1), 3.30 p.m.
- 13 Thurs. General Practice Review Committee, 11 a.m.
- 19 Wed. Joint meeting of B.M.A. and T.U.C. Committees, 11 a.m. (Preliminary meeting of B.M.A. Representatives, 10.15 a.m.)
- 26 Wed. Council, 10 a.m.
- 27 Thurs. Council.

APRIL

- 2 Wed. General Practice Review Committee, 11 a.m.
- 16 Wed. General Practice Review Committee, 11 a.m.

Branch and Division Meetings to be Held

BLACKPOOL AND FYLDE DIVISION.—At Savoy Hotel, Gynn Square, Blackpool, Wednesday, February 13, 7.15 for 7.30 p.m., dinner; 8.30 p.m., lecture by Dr. F. Storey Cliff: "Some Rural Skin Diseases."

BURTON-ON-TRENT DIVISION.—At Stanhope Arms Hotel, Bretby, Wednesday, February 13, 7.45 p.m., dinner, followed by lecture by Brigadier R. A. Broderick: "Ulcers of the Mouth and Allied Conditions."

CITY DIVISION.—At Mildmay Mission Hospital, Austin Street, Bethnal Green, London, E., Tuesday, February 12, 8.30 p.m., clinical meeting.

CROYDON DIVISION.—At Croydon General Hospital, Tuesday, February 12, 8.30 p.m., general meeting. Address by Dr. J. G. Humble: "Recent Advances in the Diagnosis and Treatment of Anaemias."

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Thursday, February 14, 8.30 p.m., address by Dr. R. M. Mason: "Cortisone."

HENDON DIVISION.—At Hendon Hall Hotel, London, N.W., Tuesday, February 12, 8.45 p.m., Dr. W. J. O'Donovan: "Drug Rashes."

ISLE OF WIGHT DIVISION.—At St. Mary's Hospital, Newport, Sunday, February 17, 3 p.m., clinical demonstration by Dr. J. C. Harland: "Heart Failure." All Island practitioners are invited.

KINGSTON-ON-THAMES DIVISION.—At Kingston Hospital, Wolverston Avenue, Kingston-on-Thames, Tuesday, February 12, 8 for 8.30 p.m., Mr. R. C. Brock: "Cardiac Surgery." A film and slides will be shown.

LEIGH DIVISION.—At Boar's Head Hotel, Leigh, Tuesday, February 12, 8.30 p.m., address by Mr. J. Kilshaw, A.I.B.P., A.R.P.S.: "Medical Photography in the Teaching Hospital."

ROCHDALE DIVISION.—At Red Lion Hotel, Lord Street, Rochdale, Monday, February 11, 8.30 p.m., meeting to discuss subject of inflation of doctors' lists.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships, as follows:

An Ernest Hart Memorial Scholarship, of the value of £250.

A Walter Dixon Scholarship, of the value of £250.

Four Research Scholarships, each of the value of £200.

These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease.

Each scholarship is tenable for one year, commencing on October 1, 1952. A scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research, but may be a member of H.M. Forces or may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment will not, in the opinion of the Science Committee, interfere with his or her work as a scholar.

Applications for scholarships must be made not later than March 31, 1952, on the prescribed form, a copy of which will be supplied on application to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Diary of Central Meetings

FEBRUARY

- 12 Tues. Central Ethical Committee, 2 p.m.
- 12 Tues. Subcommittee on Constitution and Procedure of Medical Service Committees, General Medical Services Committee, 2 p.m.

- 15 Fri. Ophthalmic Group Committee, 2 p.m.

A new preparation of
Aspirin
for
Children

A SAFE AND ACCURATE DOSE OF ASPIRIN—There is little fear of an anxious mother giving too large a dose of Angiers Junior Aspirin for Children. Each tablet contains $1\frac{1}{4}$ grains of Aspirin.

IN AN EASY TO TAKE TABLET—The pleasant orange flavour and sweetening in this small pink tablet makes Angiers Junior Aspirin acceptable to children even if sucked or chewed.

WITH A SAFEGUARD AGAINST GASTRIC IRRITATION—The combination of di-calcium phosphate with the aspirin guards against any irritation caused by the acid effect of the aspirin.

Acid. Acetylsalicylic. 1.25 grains. Di-Calcium Phosphate 1.50 grains, sweetening and orange flavouring to taste.

Bottles of 50 tablets 1/6

What's so different
 about Trufood?

Humanised Trufood is different. It is not an ordinary dried cow's milk. Cow's milk is certainly the raw material used but the finished product is much more than dried cow's milk: it is a special food, specifically designed to meet the nutritional needs of the growing infant. Moreover Trufood is dried by the spray process, keeping the fat as a fine, well diffused emulsion and ensuring greater solubility.

TRUFOOD

REGD.

If you would like to know more about Trufood—how it is made, and why we think that it is the most satisfactory substitute for breast milk—write to Trufood Ltd., Professional Information Service, Green Bank, London, E.1.

Invalid Bovril is a highly concentrated form of Bovril for use in the sick-room.

Prepared without seasoning, it provides the maximum concentration in the most easily assimilated form. Many doctors recommend it in cases where the patient needs "building-up" after illness. Perhaps there is a patient of yours who would benefit from a course of Invalid Bovril?

ROBINSON'S

Robsoup

THE NEW WEANING FOOD
FOR BABIES

ROBSOUP is a concentrated bone and vegetable soup, ready cooked in powder form. The food constituents are different from and complementary to those of milk mixtures and cereals.

Robsoup mixes instantly with water at all temperatures to any consistency from a thin broth, suitable for adding to the baby's bottle, to a thick soup which may be fed from cup and spoon.

Robsoup is simple to use and economical—a 1/6d. tin gives ten helpings for a baby of five months. There is no waste with Robsoup. Only the amount required for the next meal is mixed at any one time. Being a dry powder, what is left in the tin will not go bad.

Therefore, provided the water used for mixing has been boiled and the cup and spoon are clean, Robsoup is safe from the danger of food infection and will not occasion gastro-enteritis.

Robsoup is made by a new process from peas, potatoes, carrots, yeast extract, cabbage, gelatin, edible bone phosphate, salt and onion. It is rich in iron (12 mg. per 100 gms.), calcium (400 mg. per 100 gms.) and vegetable protein (15.5%). Robsoup may therefore be given either as the first addition to milk or as the next step in weaning after the introduction of a cereal. Extensive tests have shown that babies thrive on Robsoup and like its flavour.

Write for free trial tin and descriptive leaflet to Dept. MH36:—

Pregnancy and Lactation

During pregnancy Andrews Liver Salt will be found of great service. Its pleasant taste and refreshing qualities make it an acceptable draught, which can be repeated with advantage two or three times a day if necessary. Taken thus, Andrews obviates the tendency to constipation, and also relieves hepatic congestion. In the persistent vomiting of pregnancy the

sedative effect of Andrews will be found helpful, and its aperient action is of great value in cases of renal insufficiency. During lactation, Andrews can be used with confidence for the relief of constipation.

Active constituents:

Tartaric Acid ..	24.600%
Sodium Bicarbonate	25.142%
Magnesium Sulphate (B.P.C. Exsicc.)	19.000%
Sugar	31.250%
Saccharin	0.008%

A MEDICAL SAMPLE IS AVAILABLE FREE ON REQUEST

LIVER SALT

Quiet Contribution...

It's remarkable what a disturbing noise cubicle curtains can make, especially at night. That's because the supporting tube echoes the noise of the curtain rings or runners. To cut this noise, HUNTLAND cubicle rails are *air-insulated* from their supporting tubes. This has the added advantage of allowing two rails to be attached to one tube where curtains lap — making a row of cubicles look far neater. Another HUNTLAND special feature is the 'big roller, little roller' principle which prevents jamming—making curtain-drawing quick and easy as well as quiet. That's why most modern hospitals already have HUNTLAND Cubicle Rails. How about yours?

HUNTLAND Cubicle Rails

JAEGER

Jaeger body-belts are made of pure wool, for these reasons. Wool keeps its wearer cool in summer, warm in winter. Wool disposes quickly of perspiration, retaining body warmth. Wool, being porous, allows both the escape of exhalations from the skin, and the access of pure air to the skin. Jaeger body-belts sit well, stay in position, and give support without pressure. They are available in all sizes.

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R." practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R." practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R." practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R." practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held; £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not Registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement

A car is essential. Travelling and subsistence allowances for an "outside post" will be paid. Application forms and further particulars can be obtained from the County Medical Officer, County Hall, Hertford, to whom they should be returned within 14 days of the publication of this advert. (7858)

ISLE OF WIGHT COUNTY COUNCIL

Applications are invited from registered medical practitioners, men or women, for appointment as
ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER
Candidates should possess D.P.H. or D.C.H. and experience in the ascertainment of educationally retarded children will be an advantage. Salary will be on the scale £850 rising by annual increments of £50 to a maximum of £1,150 per annum. The person appointed will be entitled to a travelling allowance on the Council's scale for the use of car. Duties will be mainly in connexion with Maternity and Child Welfare and School Medical Services, together with such other duties as may from time to time be assigned by the County Medical Officer. Forms of application, obtainable from the undersigned, should be returned completed, together with a copy of one recent testimonial, and the names of two persons to whom reference may be made, not later than February 21, 1952.—L. H. Barnes, Clerk of the County Council, County Hall, Newport, I.W. (7368)

LINCOLN, COUNTY OF—PARTS OF LINDSEY ASS. COUNTY MEDICAL OFFICER AND DISTRICT MEDICAL OFFICER OF HEALTH for Horncastle Rural, Horncastle Urban and Woodhall Spa Urban Districts

Applications are invited from any duly qualified medical practitioner registered in the *Medical Register* as the holder of a Diploma in Sanitary Science, Public Health or State Medicine, for the above-mentioned combined appointments providing whole-time employment. The combined salary will commence at £1,000 2s. 1d. per annum and will rise by four annual increments of £52 12s. 1d. and two annual increments of £42 3s. 9d. to a maximum of £1,334 17s. 11d. per annum. Travelling allowances according to the County Council's scale will be paid. The appointment of District Medical Officer of Health will be made by the District Councils in accordance with the Local Government Act, 1933, and the Sanitary Officers' (Outside London) Regulations, 1935, as amended by the Sanitary Officers' (Outside London) Regulations, 1951. The appointment will be superannuable. Applications, on forms obtainable from the Clerk of the County Council, County Offices, Lincoln, must be returned not later than ten days after the appearance of this advertisement.—H. Copland, Clerk of the Lindsey County Council, Lincoln. (7846)

NORTH RIDING OF YORKSHIRE

Applications are invited from suitably qualified medical practitioners for the whole-time mixed appointment of

MEDICAL OFFICER OF HEALTH

to the Borough of Richmond and to the Rural Districts of Croft, Richmond and Startforth, and **ASSISTANT COUNTY MEDICAL OFFICER**
The successful applicant may later be required to undertake the duties of Medical Officer of Health for the Reeth Rural District. The salary paid and conditions of service will be in accordance with the recommendations of Medical Council Committee C., and at present is £1,372 10s. 11d., rising by annual increments to £1,699 13s. 10d. A travelling allowance on the County Council's scale will be paid for a car not exceeding 10 h.p. Medical examination necessary as post superannuable. Private practice not permitted. Office accommodation available. The appointment will be determinable by the officer by three months' notice in writing and by the Councils concerned with the consent of the Minister of Health at pleasure. The Health Committee are proposing to erect a house at Richmond for the officer appointed and he will be required to reside therein and to pay an economic rent. Forms of application, etc., may be obtained from the undersigned. Canvassing in any form prohibited. Last day for receipt of applications February 23, 1952.—H. G. Thornley, Clerk of the County Council, County Hall, Northallerton. (7795)

INDUSTRIAL APPOINTMENTS**FACTORY DOCTORS**
Factories Acts, 1937 and 1948.

The following appointment as Appointed Factory Doctor under the Factories Acts, 1937 and 1948, is vacant. Gatehouse, in the County of Kirkcudbright. Applications, which should be received not later than February 23, 1952, should be sent to the Chief Inspector of Factories, 8, St. James's Square, London, S.W.1.

LEVLOR BROTHERS AND UNILEVER LIMITED.

—Applications are invited from registered medical practitioners of either sex for the full-time post of **Assistant Medical Officer** at the head office. The successful candidate will be required to assist the head office staff Medical Officer in the health supervision of a large clerical staff, a considerable proportion of whom are adolescents. The work will also include the medical examination of candidates for home and overseas appointments, the re-examination of employees and their families on home leave from both temperate and tropical climates and the health supervision of certain nearby small industrial units. Candidates should have a good standard of clinical medicine combined with an interest in preventive and industrial medicine. Commencing salary will be in accordance with experience, qualifications and age, and will be not less than £1,100 per annum. Letters of application, which should include the names of three persons to whom reference may be made and full details of the candidate's training and career, should be submitted not later than February 23, 1952, to the Principal Medical Officer, Unilever House, London, E.C.4. (7786)

HERTFORD BRITISH HOSPITAL

48, Rue de Villiers, Levallois-Perret (Seine), France

Applications are invited for post of

RESIDENT MEDICAL OFFICER

tenable for six months. Hospital comprises 37 beds, including five in obstetrical unit. Salary £400 per annum plus emoluments. Post will shortly be vacant. Knowledge of French essential. Applications should be addressed to the Secretary. (7908)

COLONIAL MEDICAL RESEARCH

STUDENTSHIPS

The Secretary of State for the Colonies proposes to offer in 1952 a limited number of Postgraduate Studentships tenable at a British University or research institute or organization, either in the United Kingdom or overseas, for periods of up to two years in preparation for research appointments in the Colonial territories in the field of medicine and its cognate sciences. It would be a condition of the award that the student undertakes, if so required within the period of six months following the conclusion of the studentship period, to serve in a research appointment in any Colonial territory selected by the Secretary of State for not less than three years. **Qualifications:** Candidates should be under 32 years of age and should hold either (a) a medical qualification registrable in the United Kingdom, or (b) a first or good second-class honours degree. A candidate taking a degree this summer may apply before the result of the degree examination is known. **Allowances:** (a) For students with medical qualifications a maintenance allowance is payable in the scale £565 by £35 to £740 per annum, the starting point being determined by the number of years' experience gained since qualification. The allowance is taxable and marriage and children's allowances are not payable in addition. (b) For non-medically qualified students a maintenance allowance is payable at the rate of £300 per annum (£360 per annum if training is at Oxford, Cambridge, or London) with the addition for a married student of £110 marriage allowance plus children's allowances. These allowances are tax free. Provision is made separately for payment of fees. Application forms are obtainable from Under Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1. Completed applications should reach the Colonial Office not later than March 31, 1952. (7729)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

PATHOLOGIST

for the Colonial Medical Service in Malaya

Duties include research work and the administration of the laboratory, diagnostic examination of pathological and bacteriological specimens, post-mortem examinations and some medical work. Appointment is available: (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity: (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There is also a cost-of-living allowance at varying rates, according to family circumstances, with minimum of £336 per annum for single men, rising to maximum of £707 per annum for married men with children. **Note.** Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience, and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity granted refer to doctors eligible for "expatriate terms" under Malayan Regulations (e.g. whose permanent homes are in the United

Kingdom, Ireland, Australia, Canada, etc.). A limited number of doctors liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Candidates must have medical qualifications registrable in the United Kingdom and should have at least two years' experience of clinical pathology, general bacteriology, and particularly of morbid histology and give evidence of ability to undertake research. Application forms can be obtained from the Director of Recruitment (Colonial Service) Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/318/51). (7847)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

RADIOLOGISTS

for the Colonial Medical Service in Malaya

Duties include those of Medical Officer and hospital radiologist. Candidates must possess medical qualifications registrable in the United Kingdom and should have either a Diploma in Medical Radiology or considerable experience in radiological work. Appointment can be made: (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity: (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale 1952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There is also a cost-of-living allowance at varying rates, according to family circumstances, with minimum of £336 per annum for single men, rising to maximum of £707 per annum for married men with children (both rates rather higher when stationed in Singapore). **Note.** Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience, and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity granted refer to doctors eligible for expatriate terms under Malayan Regulations (e.g. whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). A limited number of doctors liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/194/51). (7848)

Overseas—contd.

HIS MAJESTY'S COLONIAL SERVICE, Malaya
SENIOR NUTRITION OFFICER

Required in Malaya to take charge of the Division of Nutrition, Institute for Medical Research. The officer selected will be required to organize and lead all nutrition research based on the Institute, but may have to work in laboratory, hospital or anywhere in the field; to give technical advice to the Government and Medical Services; he may, in due course, be required to organize training courses for doctors and others in the principles of nutrition. Biochemistry, bacteriology and pathology divisions are available to assist with investigations requiring laboratory facilities. Appointment, subject to three years' probation, is available on a permanent basis with pension (non-contributory) at the age of 55, or on short-term agreement for three years in the first instance. Doctors in the National Health Service may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malayan salary on leaving Malaya, at the end of their engagement. Doctors so appointed may be considered for permanent terms at any time during their employment. Basic salary is \$1,050 per mensem (£1,470 per annum). In addition, pensionable expatriation pay is payable at \$200 per mensem (£280 per annum). There is also a cost-of-living allowance at \$240 per mensem (£336 per annum) for single officers, \$430 per mensem (£602 per annum) for married officers without dependent children, and \$505 per mensem (£707 per annum) for married officers with one or more dependent children. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. Candidates must possess medical qualifications registrable in the United Kingdom and should have a higher medical qualification, with at least ten years' postgraduate experience, and an expert knowledge of, and research experience in, the science and practice of nutrition. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/344/51). (7745)

HIS MAJESTY'S COLONIAL SERVICE, Malaya
Blood Transfusion Service
MEDICAL OFFICER

Required for service in Malaya, to organize and supervise a hospital blood transfusion service for approximately a 1,000-bedded hospital. Appointment is available: (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity: (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There is also a cost-of-living allowance at varying rates, according to family circumstances, with minimum of £707 per annum for married men with children (both rates rather higher when stationed in Singapore). **Note.** Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience, and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity granted refer to doctors eligible for expatriate terms under Malayan Regulations (e.g., whose permanent homes are in the

United Kingdom, Ireland, Australia, Canada, etc.). A limited number of doctors liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Candidates must possess medical qualifications registrable in the United Kingdom, and have had at least two years' postgraduate experience in the latest technique of blood transfusion work. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/162/51). (7849)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom with one or more years' experience after qualification are required for appointment as

MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH**for General Medical and Health duties**

Appointment is available (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). **Note.** Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a), including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a), including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity granted refer to doctors eligible for expatriate terms under Malayan Regulations (i.e., those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/242/51). (5187)

HIS MAJESTY'S COLONIAL SERVICE, Trinidad
The Medical Department in Trinidad require a SUPERVISOR OF LABORATORIES, and a PATHOLOGIST

Duties of the posts are as follows: (a) **Supervisor of Laboratories.** To administer the central medical laboratory; to supervise and be responsible for the administration and technical direction of other branch laboratories; to carry out the work of a pathologist and bacteriologist and perform such other general duties as may be required. (b) **Pathologist.** To carry out, under the direction of the Supervisor of Laboratories, the supervisory and routine duties in clinical pathology, biochemistry, bacteriology and serology, haematology, morbid anatomy, histology and post-mortem work. Appointments can be made on a permanent basis with pension (non-contributory) at age of 55, or on short-term contract with gratuity on completion of satisfactory service. Candidates in the National Health Service may resign from the National Health Service but retain their superannuation rights during their time in Trinidad (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Trinidad salary on leaving Trinidad at the end of their engagement. Salary for Supervisor of Laboratories is \$6,480 (£1,350) per annum. Salary scale for Pathologist ranges from \$5,280 to \$5,760 (£1,000 to £1,200) per annum—ne dollar equals 4s. 2d. Starting point in the scale is determined according to the candidate's qualifications and experience. Quarters are not provided, but an allowance is payable towards the rental of a private house. Free passages provided for officer, wife and children, not exceeding five persons in all on first appointment, and up to three adult fares on leave. Income tax at local rates. Tour of service is three years. Generous home leave of 20 per cent of the aggregate of their salary on leaving Trinidad is provided. **Qualifications:** Candidates for appointment as Supervisor of Laboratories must have had postgraduate experience in all branches of clinical pathology. Those who have specialized in pathological histology are preferred. Experience in the tropics or the possession of the Diploma in Tropical Medicine is essential. A higher degree in medicine is desirable. Candidates for appointment as Pathologist should have a good knowledge and practical experience of modern clinical and general pathology, medical biochemistry as applied to clinical pathology and routine laboratory bacteriological work. The possession of the Diploma of Clinical Pathology or Diploma in Public Health, though not essential, would be regarded as an additional qualification. All candidates must possess medical qualifications registrable in the United Kingdom. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, (quoting reference No. 27215/329/51). (7850)

UNIVERSITY APPOINTMENTS**NUFFIELD FOUNDATION**
MEDICAL FELLOWSHIPS

As part of its programme for the advancement of health the Nuffield Foundation is prepared to award a number of Fellowships to highly qualified medical men and women of the United Kingdom, usually between the ages of 25 and 35, who wish to train further for teaching and research appointments in any branch of medicine. Between equally qualified applicants preference will be given to those who wish to pursue an academic career in child health, social medicine, industrial health, psychiatry, and chronic rheumatism. Applications for awards in 1952 must be received not later than May 1, 1952. The value of the awards will be variable but will not be less than £900 per annum plus travelling expenses. The conditions of these fellowships and the application forms are obtainable from the Secretary, The Nuffield Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1. —L. Farrer-Brown, Secretary of the Nuffield Foundation. (7796)

UNIVERSITY OF EDINBURGH
Department of Physiology

Applications are invited for the appointment of
LECTURER (Higher salary scale) and of a LECTURER (Lower salary scale)
in the Department of Physiology

The duties will include lecturing and demonstrating to medical and to science students. A medical qualification is not essential, but candidates should possess a good Honours Degree in Physiology. Salary scales £850 to £1,250 per annum, and £600 to £800 per annum respectively, with placement according to age and experience, and with superannuation benefit and family allowance where applicable. The successful candidates will be expected to take up duty on October 1, 1952. Further particulars may be obtained from the undersigned, with whom applications, giving the names of three referees, should be lodged not later than March 31, 1952.—Charles H. Stewart, Secretary, to the University. (7746)

University Appointments—contd.

GONVILLE AND CAIUS COLLEGE, Cambridge
BERKELEY BYE-FELLOWSHIP

(Founded in memory of Sir G. H. A. Comyns Berkeley and of his wife, Ethel Rose Berkeley)

The Council of Gonville and Caius College invite applications for a Berkeley Bye-Fellowship for research in either of the following fields (1) Medicine, (2) Any branch of Natural Science, excluding Medicine. Candidates should be men of not less than twenty-six years of age. The tenure of the Bye-Fellowship is from one to three years and the emolument from £500 to £1,000, according to standing. Full particulars may be obtained from the Registry, Gonville and Caius College, Cambridge. Applications must be received not later than April 1, 1952. (7851)

INSTITUTE OF UROLOGY

In Association with St. Peter's and St. Paul's Hospitals

PART-TIME BIOCHEMIST

(Medical qualification not essential)

Required to undertake research and laboratory investigation in connexion with urological disease. Graduates of at least two years' standing may apply. Appointment (approximately half-time) might suit applicant engaged in preparing thesis for higher degree. Salary commencing at £450 per annum. App'y, Secretary, St. Paul's Hospital, Institute of Urology, Endell Street, W.C.2, stating age, qualifications and experience, and enclosing copies of two recent testimonials. Closing date February 25, 1952. (7787)

TUNSTALL HALL COLLEGE, MARKET DRAYTON, SHROPSHIRE. Girls' Country Boarding School, beautifully situated in lovely parks and woodlands. Within easy access to railway station. Full curriculum for certificate of education. All extras. Own riding school, fourteen horses. Fees 48 gns. a term. For illustrated prospectus apply Principal.

TANCRED'S STUDENTSHIPS
Divinity, Medicine, Law

£100 per annum each. For men only

About Whitsuntide next the Governors propose to elect one Student in Physic at Gonville and Caius College, Cambridge, and one Student in Law at Lincoln's Inn. Candidates must have been born in England, Scotland or Wales and be members of the Church of England and unmarried. An examination will be held at Caius College on Wednesday, April 16, 1952, for Physic candidates who must be within the ages of 17 and 22 years. The Law candidates, who must be within the ages of 20 and 23 years, must have passed an approved examination of school certificate standard. The last day for sending in petitions for the Physic and Law Studentships is March 11, 1952.

A Divinity Studentship will be awarded later in the year, on the result of the scholarship examinations conducted in December by the Queen's, Christ's, St. John's, Emmanuel and Sidney Sussex Group of Colleges, in the University of Cambridge. A further announcement relating to the Divinity Studentship will appear in this Journal in September.

Apply for further particulars and form of petition, stating kind of Studentship and mentioning this Journal, to the Clerk, R. M. C. Howard, Esq., D.S.O., 28, Lincoln's Inn Fields, London, W.C.2. (7788)

Educational—contd.**ROYAL COLLEGE OF PHYSICIANS OF LONDON**

The next Examination for the Membership will commence on Monday, March 24, 1952. Prospective candidates are asked to note that entries accompanied by the certificates and testimonials required by the bye-laws must reach the College not later than first post on Monday, February 25, 1952. Candidates must have been qualified for eighteen months. Candidates who propose to submit published work under the regulations are required to give twenty-eight days' notice, and should apply, in writing, to the Registrar, without delay, for detailed instructions as to the procedure they should follow. Completed entries for published work must also reach the College not later than first post on Monday, February 25.—Harold Boldero, D.M., Registrar, Pall Mall East, London, S.W.1. (7731)

LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Victor Henry Springett, E.q., M.D., will deliver the Milroy Lectures on Tuesday, February 12, and Thursday, February 14, 1952, at 5 p.m. at the College, Pall Mall East, S.W.1. Subject: "An Interpretation of Statistical Trends in Tuberculosis." Any member of the medical profession admitted on presentation of card. By order of the President.—Harold Boldero, Registrar. (7800)

UNIVERSITY OF LONDON. A COURSE OF two lectures on "The Physics and Chemistry of Molecular Interactions at Interfaces, with special reference to haemolysis, lipo-protein associations, fat emulsion systems and the possible mode of action of some biologically active molecules," will be given by Dr. J. H. Schurman (Cambridge), at 5.30 p.m. on February 20 and 21, at the Institute of Education (Assembly Hall), Malet Street, W.C.1. Admission free, without ticket.—James Henderson, Academic Registrar.

When coughing causes insomnia

IN TRACHEITIS and bronchitis the sleeplessness caused by a persistent, unproductive cough can be very exhausting. Tusana Cocillana Cough Linctus is very valuable in such cases. It provides a blend of expectorants to loosen the tenacious mucus in the upper air passages and the central sedative, codeine, to depress the cough reflex.

By breaking the vicious circle of coughing and irritation, Tusana allows the patient to sleep and gather strength for recovery. The tendency of codeine to cause constipation is offset by the inclusion of a little extract of senna in the formula.

Supplied in bottles of 4 fl. oz.

Oral Iron Therapy

The main disadvantage with the majority of oral iron preparations is that they cause gastro-intestinal disturbance. It is thus often impossible to administer sufficient iron by the oral route fully to restore the hæmoglobin level to normal. Colloidal ferric hydroxide in the form of Colliron overcomes this great disadvantage as the iron is presented in a non-irritant form and is readily tolerated even in large dosage over a prolonged period.

OUTSTANDING ADVANTAGES OF COLLIRON INCLUDE:—

- 1 *It is pleasant to take.*
- 2 *It very rarely causes gastro-intestinal disturbance.*
- 3 *The iron is present in a non-irritant form.*
- 4 *It is suitable for prolonged therapy even in young children or infants.*
- 5 *It does not stain the teeth.*

PRESENTATION *Bottles of 4 fl. oz. and 8 fl. oz. Dropper bottles of 30 ml.*

The special dropper bottle is available for prescribing Colliron to infants

Relief of pain

'EDRISAL'

the dual-action analgesic

relieves pain—elevates mood

Headache associated with hypertension is often of psychological origin and may be treated by reassurance and an atmosphere of confidence. Severe paroxysmal headache, especially in malignant hypertension, may however be very difficult to relieve. In these cases 'Edrisal' is often of value; its dual action relieves pain and ameliorates mood, relieving depression and lessening the patient's preoccupation with his symptoms.

Each tablet contains: Amphetamine ('Benzedrine') sulphate 2.5 mg., acetylsalicylic acid 160 mg. (gr. 2½), phenacetin 160 mg. (gr. 2½).

MENLEY & JAMES, LIMITED, COLDHARBOUR LANE, LONDON, S.E.5

*Here is the
patient who can
benefit most from*

VERILOID^{Trade Mark}

IN HYPERTENSION

The patient with moderate hypertension, constituting the great bulk of hypertensives seen clinically, is the one that can benefit most from Veriloid. In his management, dosage is more simple, and the clinical response is as a rule excellent.

By controlling hypertension in its earlier stages, much can be accomplished. Many organic changes directly related to a sustained elevation of blood pressure can be prevented, expanding the years of physical and mental usefulness of the patient.

Veriloid — a distinctive, biologically standardised fraction of *Veratrum viride* — exerts its well-defined hypotensive action without sacrifice of postural reflexes so important for comfortable living. The average daily dose of from 9 to 15 mg. given in divided doses three times a day usually produces a significant, sustained reduction in arterial tension. For optimal results, dosage should be carefully adjusted to the needs and tolerance of the individual patient.

Veriloid is available on prescription only through all pharmacies in 1.0 mg. tablets in bottles of 100 and may be prescribed on Form E.C.10 without restriction. Literature available on request.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 16 1952

RHEUMATIC DISEASES IN THE U.S.A.*

BY

J. J. R. DUTHIE, M.B., F.R.C.P.Ed.

Senior Lecturer in Rheumatic Diseases, Department of Medicine, University of Edinburgh

Clinics and Hospital Facilities for Rheumatic Diseases

The publication in 1949 of a survey of research on rheumatic diseases in the United States by a committee of the National Research Council provided ample evidence that the rheumatic diseases constituted a major social and economic problem. In its final report the committee says that the most common cause of chronic illness in the United States is the group of rheumatic diseases. They estimated that some 7,500,000 Americans suffer from arthritis or some other form of rheumatism, and that 30,000,000 people, counting the families of arthritics, are concerned with the medical, social, and economic aspects of this problem. In 1939, 97,200,000 days of work were lost as a result of rheumatism, amounting to a financial loss of \$500,000,000 a year. The estimated yearly cost of medical care was \$100,000,000.

In 1949 there were only 65 specially endowed beds for arthritic patients in the United States as opposed to 100,000 free beds for patients suffering from tuberculosis. There would appear to have been little change in the position since the time of the committee's report. It was found that in the majority of hospitals visited clinics have been established, staffed by physicians with a special interest in rheumatic diseases, but few beds are available for patients in need of hospital care. As a rule patients are referred to these clinics from the medical out-patient department or from the medical and surgical services of the hospital for consultation. A proportion remain under the care of the clinic for treatment, the remainder being returned to the referring service. In the case of patients requiring in-patient care, admission to beds in the general medical wards is arranged, and treatment is carried out along the lines indicated by the physician in charge of the rheumatic clinic. Responsibility for these cases, however, is borne by the visiting physician to whose ward they have been admitted.

Few of the physicians who have made a special study of rheumatic diseases have direct charge of beds. This arrangement arises from the belief held by most physicians in America that the chronic rheumatic diseases form an integral part of the field of general medicine, and that their segregation in special wards or units would

be a retrograde step, leading to undue specialization on the part of doctors in charge of such units, to their detriment as general physicians. Experience in Britain would suggest that from the point of view of the arthritic patient there is a real need for a limited number of such special units, where the problems of treatment can be studied and research carried on under unified control. It must be borne in mind, however, that the development of such units in America presents a much more difficult problem on account of the high cost of hospital care and the limited number of free beds. In a number of the teaching hospitals State grants are available which enable selected patients to be admitted for long-term study and treatment. Twenty such State beds are available in the Massachusetts General Hospital, Boston, in the arthritis service directed by Dr. Walter Bauer.

An exception to the general rule is the Robert Breck Brigham Hospital, Boston, where some 30 beds are available in the public wards for rheumatic patients. Even in this specially endowed hospital, rising costs have led to a reduction in the number of beds, and there are few non-paying patients even in the public wards. Application for admission to this hospital is made by the patient's own doctor, who gives details of the clinical and financial status of the patient. Patients are followed up after discharge in home service clinics run by the eight physicians on the visiting staff. This hospital provides a very complete service for rheumatic patients, including orthopaedic and surgical care, and it appears to be the only institution of its kind in America.

Arthritis and Rheumatism Foundation

Mention must be made at this point of the Arthritis and Rheumatism Foundation, which was incorporated in 1948 with the following purposes: "To formulate and carry out a national program of research and education in the rheumatic diseases in order to discover the causes and to develop methods of prevention. To promote on the local level more effective methods of diagnosis for sufferers, more facilities for treatment and for training physicians in rheumatic diseases. To provide systematic re-training and rehabilitation for those disabled by rheumatic diseases."

By 1950 eighteen Chapters of the Foundation had been organized throughout the nation and appeals for funds successfully launched. In New England considerable progress has been made by the Chapter in organizing

*Report on tour of rheumatic centres in the U.S.A. from May 30 to June 28, 1951. The tour was made possible by a World Health Organization Fellowship.

a programme of information for physicians, in the form of lectures and clinical demonstrations and the distribution of scientific literature; in the award of clinical fellowships to doctors practising in more remote districts to enable them to pursue special studies at a teaching centre for three months to a year; in providing financial support and professional service to arthritis clinics in country districts; and in aiding patients to obtain admission to hospital. The activities of the New England Chapter are guided by a whole-time medical director, who is advised by a medical and scientific committee. If Chapters in other States are meeting with a similar degree of success, the activities of the Arthritis and Rheumatism Foundation will do much to better the lot of sufferers from rheumatism in the States, who might otherwise experience considerable difficulty in obtaining early and adequate treatment.

Interest in Chronic Rheumatism

The advent of cortisone and A.C.T.H. has done much to arouse interest, both lay and medical, in chronic rheumatism in the United States, and considerable sums of money are now available for research. It is felt, however, that, owing to the structure of hospital organization and the rising cost of in-patient treatment in the States, there are too few beds available for severely affected patients requiring more detailed study and prolonged treatment. The administration of cortisone by mouth has proved very effective in the suppression of symptoms even in severely incapacitated patients. Oral cortisone is now available on prescription throughout the country, and it is felt that its indiscriminate use on an out-patient basis may temporarily obscure the need for more adequate provision of hospital accommodation for the rheumatic diseases. The limitations and risks of long-term cortisone therapy will be discussed later, but it may be said at this point that the hopes aroused by the first reports of its use in rheumatoid arthritis, that an effective means of controlling the disease had become available, have not been confirmed by experience gained during the past two years.

In comparing the state of affairs in Britain with that in the United States, it is felt that the development of a limited number of special units in connexion with teaching hospitals and universities under the control of full-time physicians, which is taking place at present in Britain, is on the right lines. In the States there is as yet no evidence that such a policy is likely to be developed, for the reasons given above, although the activities of the Arthritis and Rheumatism Foundation will undoubtedly improve the facilities for the diagnosis and treatment of the rheumatic diseases.

A.C.T.H. and Cortisone in the Rheumatic Diseases

Since the report by Hench and his colleagues in the Mayo Clinic of the dramatic suppression of symptoms following the administration of compound E (cortisone) or adrenocorticotrophic hormone (A.C.T.H.) to patients suffering from rheumatoid arthritis a vast literature on the subject has accumulated. No attempt will be made to review the innumerable papers that have appeared in medical journals since 1949. It will suffice to state that the original claims have been fully substantiated by many workers all over the world. That overdosage effects of greater or lesser significance appear sooner or later in about 50% of cases was made clear by Hench in his original and subsequent papers.

The object of the present inquiry was to ascertain the opinions of experienced physicians who had been using the

hormones for the past two years on their ultimate place in the treatment of the rheumatic diseases. This question was discussed in detail with many workers, and, although considerable divergence of opinion exists both on the therapeutic value of A.C.T.H. and cortisone and on the mode of action of the adrenal steroids, an attempt will be made to review the position as fairly as possible.

First, it is universally agreed that neither A.C.T.H. nor cortisone has any curative action in disease, although in certain self-limiting conditions symptoms may apparently be completely suppressed until the disease has run its natural course—for example, in acute rheumatic fever. It is also agreed that, if high doses of either hormone are required for any length of time, overdosage effects will eventually appear. Withdrawal of either hormone is followed in most cases by a return of symptoms. In a smaller proportion of cases cessation of the administration of cortisone is followed by the severe and prolonged "post-cortisone withdrawal syndrome," which will be discussed later. With these general considerations in mind, experience of the use of the hormones in rheumatoid arthritis will be considered in more detail, as a large number of cases have now been studied in those centres where long-term trials have been run. The majority of patients have received cortisone by parenteral injection, or, more recently, by mouth, as the injection of A.C.T.H. four times daily renders its use a much less practical procedure outside hospital.

Long-term Use of Cortisone in Rheumatoid Arthritis

Rheumatoid arthritis varies in its clinical course. In the earlier stages of the disease spontaneous remissions are not uncommon, but most cases relapse and run a subacute or chronic course over many years. The rapid suppression of pain and restoration of mobility and function which followed the administration of cortisone demonstrated for the first time that symptoms could be effectively controlled even in the active stages of the disease. It was natural to think that a really effective method of treatment had become available in a disease which had previously proved singularly resistant to all forms of therapy. Experience has shown, however, that various overdosage effects may complicate the picture during prolonged administration of cortisone. Their incidence is high when the daily dose is 100 mg. or more. Under 50 mg. a day these effects become much less common. Unfortunately, only a small proportion of patients derive significant benefit in the lower dose range (25–50 mg. daily).

In most of the American series of cases some 50% have shown side-effects of one kind or another. The significance of these effects varies. Some are of little importance and are readily accepted by patients for a time without complaint—for example, mild oedema due to salt retention, rounding of the face, increased hair growth, striae, acne, disturbance of menstruation, nervousness, mild depression, headaches, dizziness, blurring of vision, tachycardia, exhaustion, insomnia, obesity due to increased appetite. In long-term administration, however, the persistence of one or more of these minor effects may so disturb the patient as to necessitate withdrawal of the hormone. Other effects are more serious. Signs of intercurrent infection may be masked. Although there is no clear evidence that cortisone inhibits the production of antibodies, it may lower the resistance of the tissues to invasion by pathogenic organisms and their toxins. This may be directly related to its ability to inhibit or suppress inflammatory reactions which are likely to form an important part of the body's defence mechanism. Cases have been reported in which such inhibition of the symptoms of infection have had serious consequences, and this constitutes one of the real hazards of cortisone therapy.

Activation of quiescent tuberculous lesions has occurred. Massive haemorrhage from the gastro-intestinal tract and perforation of peptic ulcers have been reported from several centres. In older patients fractures of the long bones and collapse of vertebral bodies constitute a real risk. Thrombo-

phlebitis, pulmonary infarction, coronary thrombosis, and major psychotic episodes are among the other less frequent but more serious complications which may occur. In the individual case which has previously been adequately controlled the underlying disease process may become more acute, and symptoms may reappear which necessitate an increase in dose from a safe to a more dangerous level. Warning of such an event may be given by an increase in sedimentation rate or a rise in circulating eosinophils, although this occurs in a fairly high proportion of long-term cases without recurrence of symptoms. In other cases a progression of the damage in the joints has been demonstrated radiologically when symptoms have remained under adequate control. It would appear, therefore, that, although pain and stiffness may be abolished with a corresponding increase in functional activity, the disease process may not be completely arrested. Under these circumstances increased function, unrestrained by pain, may cause further articular damage, the effects of which may be appreciated only at a later date.

Complications of Cortisone Withdrawal

If the administration of cortisone has to be stopped for any of the reasons given, or because of financial considerations, a significant proportion of cases suffer from what has come to be described as the "cortisone withdrawal syndrome." Symptoms may appear within a few days of withdrawal or be delayed for a week or two. These patients complain of profound weakness and exhaustion, generalized aching pain and stiffness in joints and muscles—no longer relieved by the usual doses of analgesics, made worse by activity and relieved by sleep—anorexia, mental depression, and weight loss. Similar symptoms occur after partial adrenalectomy in Cushing's disease, but do not appear to be directly related to suppression of the adrenal cortex. The electrolyte pattern may be normal and the response to A.C.T.H. adequate long before symptoms disappear, which may be a matter of weeks or even months. Excretion of 11-oxysteroids may be within the normal range. A possible explanation may be that the tissues become conditioned to a high level of circulating steroids, and symptoms arise as a result of a relative deficiency. This view is confirmed to some extent by the fact that withdrawal symptoms rarely appear unless cortisone has been given for several months. When this syndrome is accompanied by an acute exacerbation of the rheumatoid process the adverse effect on the patient's physical and mental condition may be very severe.

A much rarer complication of cortisone withdrawal has been the appearance, in several cases of rheumatoid arthritis, of the signs and symptoms of disseminated lupus erythematosus or periarteritis nodosa. None of these cases have as yet been reported in the literature, but several have been examined personally, and the case records of others have been studied. This may be further evidence in support of the possibility that in certain instances cortisone may render the tissues more vulnerable to some unknown tissue-damaging agent which may be present in the collagen group of diseases. Too much significance should not be attached to these clinical observations at this stage, but certain experimental evidence would seem to point in the same direction.

A Conservative Attitude

The accumulated experience of the use of cortisone in rheumatoid arthritis during the past two years in America has led physicians to adopt a much more conservative attitude towards its routine employment. It is no longer regarded as a substitute for other forms of treatment. It has been found that only in about one-third of the patients started on treatment can a useful suppressive effect be maintained at a dose level which causes no undue disturbance. Complete suppression of symptoms is no longer aimed at. The dose is adjusted to control pain and stiffness to an extent which will enable a reasonable functional level to be maintained. The hormone is used as an adjunct to

other forms of treatment which by themselves have failed to restore a useful degree of function. The basic regime of general supportive measures, physiotherapy, gold, and rest splints is tried for several months before cortisone is prescribed, and is continued along with cortisone. The presence of significant articular damage will limit the value of the hormone, and preference is shown for early cases in which the pathology is still potentially reversible and in which a smaller dose will suffice.

The high initial suppressive doses (200–300 mg. daily) are no longer used in many centres, including the Mayo Clinic, because it has been found that patients who have experienced complete relief in the early stages of treatment find it difficult to accept even a partial return of symptoms when the dose is lowered to a safe maintenance level. This has led to difficulty in controlling the dose level in outpatients, who may occasionally obtain additional supplies at high cost from black-market sources. The disappearance of the initial euphoria may also cause psychological disturbance both in the patient and in his relatives. The more general practice is to start with between 50 and 75 mg. daily and adjust the dose up or down during the first weeks of treatment. In those patients in whom the useful dose is unduly high, treatment can be stopped before troublesome side-effects appear. Many methods of administration have been tried—intermittent and continuous courses of cortisone alone, cortisone combined in various ways with A.C.T.H., both continuous and intermittent, reduction of the frequency of administration to once, twice, or thrice weekly, low continuous maintenance dose with occasional booster doses, and so on, but no technique has been evolved to date by which satisfactory control can be maintained in all cases without side-effects. Individuals vary widely in their requirements, and alterations in dose may often be necessary in the same patient.

Precautions in Use

Oral cortisone is now the most commonly used form. Rapid absorption from the alimentary tract takes place, and tablets (25 mg.) are given three or four times a day, preferably after meals; otherwise the rapidity of absorption may cause nervousness and inability to concentrate. The dose by mouth is generally the same as that given by intramuscular injection, although in a few patients more is required to produce the same effect by the oral route as was previously obtained by injection. Cortisone is now available in a form which can be given by intravenous injection, and trials of this preparation are under way at the present time. It was hoped that, given by this route, the effect might be more prolonged. These hopes have not been fulfilled. The therapeutic effect is good, but is not sustained.

Cortisone has been given in combination with various other substances, such as gold, para-aminobenzoic acid, ascorbic acid, insulin, oestrogens, and testosterone. No definite conclusion can be reached at the present time, but on the whole such combinations have been disappointing. Claims have been made on behalf of insulin and para-aminobenzoic acid, but these require confirmation. The administration of oestrogens may minimize side-effects, especially in post-menopausal women. Negative nitrogen balance can be corrected by testosterone, but this is seldom necessary in patients who are not on a restricted diet. Restriction of salt and the administration of potassium chloride may correct disturbances of the electrolytic balance. Antibiotics should be used in adequate doses when infection is suspected in a patient receiving cortisone. These various precautions, combined with close clinical supervision, render the use of cortisone less hazardous, but it has become clear that the use of the hormone in the long-term control of the symptoms of rheumatoid arthritis is not as yet a practical procedure. The approach must still be experimental, as has been repeatedly emphasized by Dr. Philip Hench.

If further evidence be produced to show that its effect is only to suppress symptoms, leaving the underlying disease process unchecked, then the attitude of the medical profes-

sion towards its use in inflammatory diseases of unknown aetiology may have to be revised. In rheumatoid arthritis in particular, in which marked increase in the functional use of the affected joints follows the administration of cortisone, the possibility that articular damage may be increased rather than reduced must receive careful consideration. The answer to this question can come only from detailed follow-up studies of patients given cortisone over long periods.

Some observers had noted the fact that prolonged remission tended to occur most often in those patients who had received high doses. On this basis the effect of 500 mg. of cortisone, daily has been tried on a number of cases for periods of 14-30 days. The results in terms of duration of remission following treatment have been encouraging, but all patients have eventually relapsed, and it is very doubtful if such high doses are justifiable unless clear evidence is obtained that there has been induced a fundamental alteration in the course of the disease.

The answers to many of the problems discussed will come from the continuation of the carefully controlled studies which have been going on in America during the past two years, and for a shorter period and on a smaller scale in Britain.

Short-term Use of Cortisone

Cortisone can be given in effective doses over short periods without undue risk, and in certain circumstances such a use of the hormone may serve a valuable purpose in rheumatoid arthritis. In severely ill bedridden patients running a progressively downhill course, and where the disease cannot be controlled by other means, cortisone may be used to reduce pain and spasm sufficiently to allow other forms of treatment to be applied more effectively. Deformities due to muscle spasm may be corrected and the position maintained by splints after cortisone is stopped.

Where deformities have developed owing to soft-tissue contractures, cortisone may render their correction by manipulation easier and damp down the flare which sometimes follows this procedure. Cortisone may be similarly useful when orthopaedic surgery is indicated in more advanced cases. Synovial inflammation and congestion can be lessened. Post-operative complications are reduced by the fact that physical methods of treatment can be applied early. Wound-healing is not significantly delayed by the doses required to secure these effects. Antibiotics are used routinely in these cases, and wounds are carefully watched for signs of infection.

Short courses of cortisone may thus prove a useful aid in the rehabilitation of crippled patients.

Intra-articular Injection.—That cortisone can act when applied locally has been clearly demonstrated in inflammatory conditions of the eye. Suppression of pain and swelling has followed its injection into the affected joints in rheumatoid arthritis: 25-50 mg. of cortisone acetate suspension has been used. The beneficial effect lasts four to five days on an average, but may be maintained in isolated cases for two to three weeks. Unfortunately, repeated injections appear to cause irritation and the joint tends to deteriorate. Compound F has proved much more satisfactory for this purpose. Mention will be made of this later.

Compound F.—In recent months increasing amounts of compound F have become available in the States for clinical trial. Up to date, it appears that there is no fundamental difference in the clinical effects of E and F. Occasionally it has been found that more F is required than E to produce the same effect, but this is by no means always the case. Side-effects are the same. Enough experience has not yet been gained to reach more than tentative conclusions regarding the value of compound F as compared with E when given by injection or by mouth, but for local injection into joints compound F seems much more satisfactory. Repeated injections can apparently be given without ill effect, with satisfactory suppression of local symptoms, and with no effects due to absorption from the joint. This method of

treatment may prove of real value, especially in cases crippled by pain and swelling in the weight-bearing joints. A weekly injection of 25-50 mg. is adequate in most cases. Much more experience is required before the real value of this mode of treatment can be assessed, but the preliminary results are encouraging.

A.C.T.H. in Rheumatoid Arthritis

From the therapeutic point of view, the action of A.C.T.H. in rheumatoid arthritis is similar to that of cortisone. The cortex of the adrenal gland is stimulated to produce large amounts of steroid hormone, probably compound F. A.C.T.H. is quickly destroyed, and to maintain its effect injections, subcutaneous or intramuscular, must be given every four to six hours. Attempts to produce the hormone in a vehicle which would prolong the time of absorption have not yet been completely successful. In several American clinics patients or their relatives are taught to give the injections at home, but abscesses often develop, and may remain unsuspected because of inhibition of the normal inflammatory reaction. These abscesses may be very slow to heal. More recently A.C.T.H. has been given by slow intravenous drip over a period of 8-12 hours (20-50 mg. in a pint (570 ml.) of saline). This method of administration, possible only in hospital, is more economical of material and is said to produce maximal adrenal stimulation. It was hoped that more prolonged remission of symptoms might follow, but experience to date has not been very promising in arthritis. Patients have relapsed within a few days of the cessation of daily intravenous A.C.T.H. given for two to three weeks.

Side-effects are similar to those which occur during the administration of cortisone, but there is a greater tendency for salt retention and potassium loss to occur. Clinicians have noted considerable differences in potency between batches, although there has been little variation in the results of the ascorbic-acid-depletion test of Sayers and Sayers. It may be that this test is not a reliable guide to the effectiveness of A.C.T.H. in the clinical field. These variations and the necessity for several injections daily have limited the use of A.C.T.H. in long-term treatment of rheumatoid arthritis. Suppression of symptoms is attained more quickly by A.C.T.H., and where the rapid effect is required A.C.T.H. may be preferred to cortisone. These circumstances will rarely arise in rheumatoid arthritis, but may be important in more acute diseases such as rheumatic fever. Astwood, in Boston, has evolved methods for obtaining a much purer form of A.C.T.H., and he states that some patients can be maintained in remission by a total daily amount of about 1 mg. given in three doses. Possible future developments in the use of A.C.T.H. may depend upon the availability of purer forms, prepared as long-acting substances which will reduce the number of injections required. In general the factors limiting the long-continued use of cortisone are also applicable to A.C.T.H. For short-term administration, where a rapid suppression of symptoms is the main object, A.C.T.H. is the more suitable of the two.

Research

To a person from Britain visiting centres of research in the United States the first impression is one of awe at the scale on which modern techniques are being applied to the study of basic problems in health and disease. In many university centres large laboratory buildings have been built since the war, or are in process of erection. All the basic sciences are represented in these research institutes. Equipment is on the most lavish scale, and personnel are of the highest calibre. The policy in regard to clinical research varies. In some centres the laboratories are primarily devoted to research on clinical material. In others fundamental research is given the first priority. In the latter it is felt that if the individual worker is left entirely free to pursue his basic studies there is a sufficiently strong possibility that discoveries will be made which will illuminate problems in the clinical field.

The direction of research may be in the hands of the pure scientist with an interest in medical problems, or in those of a doctor with additional scientific training. This dual approach will be fruitful in bridging the gap so commonly present between clinical and basic research. On the other hand, modern scientific techniques have become so exacting, and equipment so costly, that there is a real danger of the young scientist, whether he be a doctor of medicine or not, becoming tied to a narrow and possibly unproductive line of investigation which leaves him little time or opportunity for original thought. As someone has said, learning the technique of electron microscopy is like catching a bull by the tail. The danger that the necessity for acquiring difficult techniques may exact too great a toll on young research workers is more real in America than in Britain, where finance places distinct limits on the amount of apparatus available.

This problem has been met to a certain extent in the States by training technicians to a high degree of competence and paying salaries of an order appropriate to their skill; but this solution is only a partial one, and tends to produce an undue reliance on laboratory results reported by technicians who have no knowledge of their significance and who are not always fully aware of the limitations of the methods they have been trained to use. This point is well illustrated in connexion with the published results of work on urinary steroid excretion. The methods used in different laboratories differ fundamentally, and in actual fact no reliable techniques have as yet become available in this field, although a perusal of literature gives rise to the impression that estimations of 11-oxysteroids, 17-ketosteroids, etc., are now a matter of routine in many centres. These criticisms are of a very general nature and are not intended to detract in any way from the value of the vast amount of useful work going on in American laboratories and research institutes.

It is not intended to review in detail the work of individual groups, but merely to survey the general trend of research in the field of the rheumatic and allied diseases in America, within the limits of what can be learnt from a short visit.

Mode of Action of the Adrenal Steroids in Rheumatic Diseases

It is an undoubted fact that experience in the use of A.C.T.H. and cortisone in the clinical field has far outrun the advance in knowledge of their mode of action in the rheumatic diseases. It is a reflection of the difficulty of the problem that two years' intensive research in many centres all over the world has shed very little light on the fundamental mechanism whereby adequate amounts of the steroid hormones, whether exogenous in the form of compounds E and F, or endogenously produced by stimulation of the adrenal cortex, can largely suppress the manifestations of the disease process. The hope that a study of the action of these hormones would lead to an unravelling of the aetiological problems of the rheumatic diseases has not as yet been fulfilled. It has become clear that their action in rheumatic diseases is in no way specific. It seems to depend upon a suppression of the inflammatory process, and it has been shown that inflammation arising from many diverse agents can be similarly reduced. In other words, the action of the adrenal steroids in this respect seems to depend on a reduction of tissue reaction to injury, and bears no apparent relationship to the nature or origin of the agent responsible.

This anti-inflammatory effect can apparently be dissociated from most of the other known effects on the physiological processes of the body. It does not depend on the changes induced in electrolyte pattern, carbohydrate, protein, or fat metabolism. There is no evidence that the rheumatic diseases are associated with any deficiency in adrenal hormones. In fact, evidence of hormonal excess usually becomes evident before symptoms are adequately controlled. The action of the cortical hormones that appear to be important in relation to their therapeutic effect is their apparent ability to inhibit or damp down the reactivity of

mesenchymal tissue, which is the site of the primary injury in the rheumatic group of diseases. The fact that they are also effective in allergic or hyperimmune states suggests that one possible mode of action may be through their effect on antibody-antigen reactions. No clear evidence that such reactions are involved in the pathogenesis of rheumatic disease has yet become available.

In summing up, it can be said that, although a vast amount of knowledge of the action of the adrenal steroids on the physiology of the body has been gained since A.C.T.H. and cortisone became available, we are as yet completely ignorant of how they act in disease. Certain lines of investigation may prove productive, and some of these are discussed below in a little more detail.

Action on Immune Response

A good deal of the evidence regarding the action of the adrenal steroids on immune response is conflicting. Early work suggested that circulating antibody was increased by cortisone, by release from lymphoid tissue undergoing involution. More recent work has failed to confirm these earlier results. It seems that antibody production may be diminished under certain circumstances, but the union of antibody and antigen is not prevented. A further possibility is that the action of some product of the union of antigen and antibody is inhibited. A possibility that is in the minds of some workers is that proteolytic enzyme systems may be activated by antibody-antigen union, and that the action of the steroid hormones is to inhibit this activation. The whole subject is under intensive study in a number of laboratories and, although some interesting results have been the subject of preliminary reports, no definite proof of any of the theories outlined has as yet been obtained.

Action on Mesenchymal Tissue

It is well known that in pathological states of hyperadrenalism striae appear and wound-healing is delayed. As some degree of hyperadrenalism appears to be necessary to induce remission in the collagen group of diseases, investigation of the effect of A.C.T.H. and cortisone on connective tissue has been undertaken by a number of workers. Satisfactory evidence that fibroblastic activity is markedly depressed has been obtained in experimental animals. This so-called depression of reactivity to injury might be related to the suppression of symptoms of inflammation. On the other hand, wounds have healed satisfactorily in patients receiving doses of cortisone adequate to maintain them in good clinical remission. Cortisone has been used to facilitate orthopaedic surgery in rheumatoid arthritis without causing undue delay in wound-healing.

Little change in the histology of nodules excised before and during cortisone administration has been noted beyond a reduction in cellular infiltration. It is not yet clear, therefore, whether the action of steroids in depressing the reactivity of connective tissue to injury is in fact the explanation of their action in diseases of the collagen group.

Research into the structure of collagen, ground substance, and basement membranes by electron microscopy and microchemical methods is now beginning to provide information about the function and relationship of these components of mesenchyme. Increased knowledge of their chemical structure and physical properties, together with detailed studies of the changes induced by the steroid hormones, may well provide information of fundamental importance to the elucidation of the mode of action of cortisone in the collagen diseases. Due credit must be given to the scientists who are at present pursuing this laborious, exacting, and relatively undramatic type of research in many centres in America.

Adrenal Function in Rheumatoid Arthritis

It has already been stated that no unequivocal evidence of adrenal insufficiency has been obtained in patients suffering from rheumatoid arthritis. On the other hand, some

evidence of abnormal adrenal function has been advanced by Dobriner and his colleagues in the Sloan-Kettering Institute, New York. In comparing the steroid-excretion pattern of normals with patients suffering from rheumatoid arthritis, a striking qualitative difference has been demonstrated. Two compounds—17-hydroxy-pregnanolone and 11-hydroxy-etiocholanolone—were present in the urine of the arthritic subjects. The former abnormal metabolite has been demonstrated in cases of adrenal tumours and adrenal virilism. The latter has been found in the urine of patients with neoplastic disease. On this evidence it is tentatively concluded that abnormal function of the adrenal cortex may play a part in the pathogenesis of rheumatoid arthritis. The administration of both A.C.T.H. and cortisone causes these abnormal metabolites to disappear. This suggests the possibility that they may arise, not from an abnormal function of the adrenal cortex, but from an altered metabolism of adrenal steroids in the peripheral tissues. Much more work is necessary before a final conclusion is reached, but the results of further investigations by Dr. Dobriner and his staff will be awaited with the greatest interest.

Selye has advanced the hypothesis that an excessive output of mineralo-corticoids by the adrenal cortex may be of importance in the causation of diseases of the collagen group. He bases his theory on the demonstration in rats sensitized by the removal of one kidney, high salt intake, and D.C.A. of lesions resembling those of nephrosclerosis, periarteritis nodosa, rheumatic fever, and rheumatoid arthritis. In more recent reports he claims to have demonstrated that this suggested adrenal imbalance may be caused by an overproduction of somatotrophin or growth hormone.

No direct evidence of the existence of such a hormonal imbalance has been demonstrated in human patients. If this were correct, the administration of desoxycortone acetate (D.C.A.) to patients suffering from rheumatoid arthritis should make the disease worse. This is not the case. There is no evidence of major alteration in the electrolyte pattern in these patients, and corticosteroid levels in the urine tend to be lower than normal. D.C.A. does not oppose the anti-inflammatory action of cortisone, and stimulation of the adrenal cortex, which might be expected to cause an exacerbation of symptoms, abolishes them as effectively as cortisone. Selye suggests that A.C.T.H. may stimulate the secretion of glucocorticoids while somatotrophin may stimulate the gland to produce mineralo-corticoids, thus explaining the apparent paradox. No satisfactory evidence in support of his contention is as yet available in human subjects.

Further studies of the production and metabolism of the adrenal steroid hormones in health and disease are obviously of the greatest importance for a more complete understanding both of fundamental physiological processes and of their possible role in disease states.

Role of the Spleen

Ungar, working in the rheumatic fever research unit in Chicago, suggests that the spleen may be important as an endocrine organ. He claims that two substances, splenin A and splenin B, are produced by the spleen in certain circumstances. A small amount of splenin A is normally present in the blood, but no splenin B. He believes that splenin A is produced by the action of the adrenal hormones on the spleen and that it is important in the defence mechanism of the body. It probably acts by acceleration of the neutralization of proteolytic enzymes. He states that some of the effects of cortisone are abolished by splenectomy. Splenin B appears in the blood only in disease states, including rheumatic fever and rheumatoid arthritis. Splenin A can be synthesized by the incubation of ascorbic acid and a suspension of spleen tissue, and isolated in a crystalline form.

Ungar postulates that splenin A may be of therapeutic value in rheumatic fever, and clinical trials are being made at the present time. Preliminary results, he states, have been

encouraging, and trials on a larger scale await the preparation of a more adequate supply of splenin A, which is now being made commercially. If the anti-inflammatory effect of cortisone depends upon its action in stimulating the production of splenin A, then the undoubted fact that cortisone is effective when applied locally is difficult to explain. It is also true that A.C.T.H. and cortisone produce their effects in patients in whom the spleen has been removed, but a possible explanation might be the development of accessory spleens. Whatever the truth, the results of more extensive clinical trials of splenin A will be of great interest.

Pleuropneumonia-like Organisms in the Collagen Diseases

At the Atlantic City Conference of the American Rheumatism Association a paper was read by Wickelhausen suggesting that organisms of the pleuropneumonia group might play a part, as living antigens, in the aetiology of certain of the collagen diseases. It was claimed that these organisms could be demonstrated in the genito-urinary tract in a high percentage of cases, although they could rarely be recovered from the joints in cases of rheumatoid arthritis. On this basis, clinical trials of the newer antibiotics have been run. "Terramycin" is said to have proved the most effective. The clinical response may be of three types: (1) gradual improvement; (2) reactivation of symptoms after withdrawal of the drug; and (3) severe exacerbation after a single dose—thought to be due to destruction of the organisms, with release of antigenic material. The method of treatment adopted has been to give the antibiotic every three days and to control exacerbations in the intervals with cortisone or albumin, which reduces hypersensitivity. Careful adjustment of the dose of antibiotic is required if the best results are to be obtained.

It was felt at the conference that this report was of considerable interest, but that much further work was required before accepting the idea that the pleuropneumonia-like organisms were in fact the living antigen in collagen diseases. Newer cultural methods have shown these organisms to be present in a high proportion of healthy people, although this does not rule out the possibility that in certain circumstances they may assume a pathogenic role.

Blood Flow in Joints

Hollander and his colleagues in Philadelphia have been investigating the effect of intra-articular injections of compounds E and F on joint temperature, using copper-constantan thermocouples mounted in a needle. Compound F has been found more effective than compound E in causing a fall in temperature, which becomes evident within 24 hours and corresponds in general to a suppression of symptoms in the joint. That this effect is a local one is evidenced by the observation that the temperature in the other knee, used as a control, was unaffected. Such observations on the local changes induced by the adrenal steroids are of undoubted value in reaching an understanding of their mode of action.

Pathogenesis of Gout

Wolfson and his colleagues in Ann Arbor claim to have demonstrated an abnormally low output of 17-ketosteroids in patients suffering from gout, although this disease is most common in males in the absence of any other signs of hypoadrenalism. They postulate that androgenic function in these patients is maintained by an abnormal male sex hormone, originating from the adrenal cortex. The role of this hormone in the pathogenesis of gout may depend upon its ability to evoke hyperuricaemia. That the action of the hormone is opposed by the glucocorticoid hormones is suggested by the suppression of symptoms by the administration of A.C.T.H., and the precipitation of an acute attack on withdrawal, when the level of glucocorticoids temporarily falls below normal. Attacks of gout not uncommonly follow stress, and Wolfson postulates that the gouty patient

responds inadequately to these situations in terms of 11-oxy steroid output, and a relative deficiency of these hormones follows, preparing the way for the acute attack.

There are a good many theoretical objections to this theory, but such studies of the hormonal pattern in gout may well lead to a better understanding of this disease and provide important information regarding the function of the adrenal steroids.

Chemical Structure of Fibrinoid

Fibrinoid change in connective tissue has been regarded as the characteristic lesion in diseases of the collagen group, thus implying that fibrinoid was in some way derived from collagen or its precursors. Kantor and his associates in New York University have now been able to show by chemical and histological methods that this substance is in fact non-collagenous in origin. This observation may be of considerable importance, as it throws doubt upon the view that changes in the structure of collagen form the basis of the pathological lesions in this group of diseases. This is a good example of how the use of combined chemical and histological techniques may provide more accurate information than more conventional methods. This more dynamic approach to the elucidation of the nature of pathological change is likely to have an increasing application, as histochemical techniques are combined with electron microscopy.

Conclusion

These brief notes on research in the field of rheumatism are far from complete, but may serve to illustrate the diversity of approach and the increasing application of the disciplines of the basic sciences to the solution of problems in the field of medicine. It becomes increasingly obvious that, with advancing knowledge, opportunities for individual research are becoming more limited. The team of scientists, representing many fields of knowledge, has largely replaced the lone worker in the small laboratory. Opportunities for the brilliant individualist still exist, but the co-ordinated activities of a group with the command of many techniques seem likely to contribute more to the store of knowledge in the long run. The place of the clinician in such a team must be clearly defined. There is a tendency at the moment to relegate him to the background along with the patient from whom material for study is obtained. Unless he has additional training in some scientific field, he finds it difficult to get on terms with his laboratory colleagues. It would be unfortunate if this trend were to develop further, as the clinician must ultimately relate new knowledge to the practical problem of applying it to the treatment of disease in the human patient. The clinician must exert himself to grasp at least the principles of scientific methods used in research, and the scientist must unbend enough to make his results and their implications comprehensible to his clinical colleague. Both must consider the best interests of the sick patient when research has produced some new approach to the treatment of his disease.

The Ministry of Health has asked the Liverpool Blood Transfusion Service, together with the Manchester and Cardiff Services, to collaborate with the Medical Research Council in a survey of patients who have received transfusions of irradiated plasma or small-pool plasma, in order to compare the incidence of homologous serum jaundice in the two groups. At present irradiation with ultra-violet light is the most promising method of sterilizing plasma. A control series of cases receiving only blood will also have to be surveyed. It is proposed to provide each hospital in the region with either irradiated or small-pool plasma, but not with both, and to follow up patients who have received either after a period of five months. The survey will last three years.

THE INVOLUTION OF THE CERVIX*

BY

HUGH C. McLAREN, M.D., F.R.F.P.S.
F.R.C.S.Ed., M.R.C.O.G.

Professor of Obstetrics and Gynaecology, University of Birmingham

Are post-partum erosions normal in the involuting cervix and do they persist if untreated? The question is important, since the common treatment of erosions after delivery rests on the assumption that they are pathological and give rise to symptoms such as leucorrhoea and backache (Browne, 1946).

Clinically, the cervix often appears to have reached its nulliparous state six weeks after delivery, but a biopsy will show that the changes of pregnancy are still obvious—for example, the stroma is cellular, vascular, and oedematous, while the glands are so numerous as to appear as a honeycomb (Stieve, 1927; Fluhmann, 1948; Murphy and Herbut, 1950). In other words, from a histological point of view the cervix, six weeks after delivery, is still in a pregnant state, although involution is proceeding.

In this clinical and histological study, observations on the post-partum cervix were followed by observations on post-natal erosions which were allowed to heal without treatment. The object was to ascertain if the process of involution in cases with erosion differed materially from the normal post-partum case.

Methods of Investigation

A total of 262 patients were investigated: 121 with post-partum erosions and 141 without post-partum erosions (controls).

The following investigations were carried out approximately six weeks after delivery. First, in every case I completed a standard case-sheet with a detailed description of symptoms such as leucorrhoea and backache. Vaginal smears were then taken and a "Cusco" speculum was passed. A diagram was made outlining the portio and giving details of the amount and type of cervical mucus. The mucous plug was then removed and an endocervical specimen of mucus was taken by an ordinary throat swab for microscopy. The physical properties of the cervical mucus were observed by attempting to draw the specimen out into threads (*Spinnbarkeit*). A laryngeal punch was then used to obtain squamo-columnar biopsies, and finally the bleeding area was treated with a nasal-wire cautery.

An attempt was made to correlate simple erosions with symptoms such as backache and leucorrhoea, and therefore complications such as parametritis and fixed retroversion of the uterus were excluded by bimanual examination.

Clinical Results

1. Backache Six Weeks After Delivery

	Erosions	Controls
Total number of patients	121	141
Backache present	43 (35%)	26 (18%)
Inadequate information	14	38

Backache was present in 35% of patients with erosions and in 18% of those without erosions. It became obvious after taking a careful history from the patient and examining her back, testing its mobility, and so on, that the cervix could

*Preliminary report, read before the Birmingham and Midland Obstetrical and Gynaecological Society, Nottingham, October 13, 1950.

not possibly be the source of the pain. If the patient, for instance, located the pain as being between her shoulder-blades, if rest relieved her pain, or if her backache amounted to stiffness prior to exercise, she was excluded. Correction by this method left 18% of patients with backaches which could possibly be related to an erosion and 2% of controls. In the erosion group nine cases were included in which data concerning localization, the effect of movement, etc., were not available, so that 18% is almost certainly too high. Moreover, by following the progress of patients with backache it became more and more obvious that cervical erosions and backache could not be correlated. First of all, backache becomes uncommon after four to five months, and, secondly, its persistence does not depend on the persistence of a post-natal erosion. For example, of nine patients with persistent backache, six had healed and three had unhealed cervical erosions five months after delivery. Vice versa, persistent erosions five months after delivery were not accompanied by a high incidence of backache.

Although it is admitted that a widely split cervix with an obstetric laceration running up the lateral fornix to an indurated and tender parametrium can cause low backache (Young, 1938; Barns, 1948), it seems clear from our observations that cervical erosions, *per se*, do not give rise to backache. It follows that routine cauterization of cervical erosions for the cure of backache is unwarranted.

2. Post-natal Leucorrhoea

Considering the enormous changes in the genital tract during childbirth, it is not surprising that some women should have a vaginal discharge six weeks after delivery. It is a mistake, however, to observe mucus at the lower cervix and to assume without further study that you have discovered the source of discharge. Moreover, if removal of the mucus or mucopus at the portio uncovers an erosion it may be wrong to assume that this is a diseased cervix producing abnormal quantities of mucus or mucopus. In fact, before diagnosing leucorrhoea of cervical origin it is essential to prove that the cervix is the source of discharge.

Incidence of Vaginal Discharge.—Six weeks after delivery 34 (28%) patients with erosions complained of vaginal discharge; 21 (17%) had only traces. However, 25 (18%) post-partum controls also had vaginal discharge and 20 (14%) had traces. By elimination of traces of discharge, lochia, trichomonas vaginitis, and so on, the incidence of leucorrhoea is corrected to 17% for erosions and 9% for controls. Six weeks after delivery, therefore, 17% of patients with erosions complained of discharge, but this is not remarkable when the normal incidence is 9%. Moreover, by studying the clinical findings at the cervix and comparing them with the patient's symptoms of discharge, we shall endeavour to show that the cervix is seldom the source of discharge.

The Post-natal Mucous Plug

The physical properties and the cell content of the plug of mucus at the post-natal cervix vary greatly from case to case. There is, however, no typical mucous plug commonly seen in erosions which is not equally common in post-natal controls, so that marked erosions may secrete traces of clear mucus and, vice versa, a normal cervix may secrete abundant mucopus.

Six-weeks Casco Examination

Cervical Mucus	Erosions	Controls
Opaque plug	44	59
Trace	15	3
Translucent	30	29
Absent	17	37
Inadequate record	15	13
	121	141

Six weeks after delivery, therefore, the cervical mucous plug is usually bulky but tenacious, while an endocervical

specimen practically never resembles "mid-cycle" mucus—that is, it seldom pours out as a crystal-clear liquid and it cannot be pulled into threads. Perhaps as a result of its tenacious quality, a stream of mucus is rarely seen extending to the vulva, which might be the case if the mucus were of a "runny" character. Whether or not this explanation is valid, there is a surprising lack of correlation between the patient's symptoms of discharge and the volume of mucus at the cervix. For example:

	No Leucorrhoea	Leucorrhoea
Opaque mucous plug at portio (42 cases)	31 (74%)	11 (26%)
Clear mucus, traces, or none (61 cases)	48 (79%)	13 (21%)

It is clear, therefore, that a large mucous plug may exist without discharge at the vulva; on the other hand, a trace of clear mucus at the portio is commonly seen in patients complaining of vaginal discharge.

Microscopical specimens were taken from 100 post-natal erosions and 100 (six-weeks) controls. The important finding was that mucus which appeared clinically to be opaque or even mucopurulent often had but a few polymorphs, the smear consisting of clouds of epithelial cells of many shapes and sizes. Indeed, one-third of all the smears had no pus cells (polymorphs).

Cell-smears from erosions and controls varied from case to case, but there was no preponderance of inflammatory cells in the erosion-smears. With Papanicolaou's staining (Papanicolaou and Traut, 1943), cervical mucus was almost without exception web-like or crenated, although a few specimens were obtained which resembled typical mid-cycle mucus—that is, they had translucent and acellular mucus which presented a pattern of parallel threads.

To summarize: (1) Considering that only six weeks had elapsed since parturition it is not surprising that discharge affected normal patients and those with erosions. (2) Study of the cervical mucous plug suggests that the cervix is seldom the source of vaginal discharge.

FIG. 1.—Disappearance of cervical erosions without treatment was recorded in 30 out of 77 patients (39%) by 20 weeks and in 42 (55%) by 28 weeks. The 28 unhealed erosions have not been observed for 64 weeks, but are at present under observation.

(See text.*)

Number of cases observed with no treatment	77
Spontaneous healing	49 (64%)
Persistence over 20 weeks	28 (36%)

*The 28 unhealed erosions are at present under observation and tend to heal. The periods of observation are as follows: 20 weeks, 5 erosions; 24, 2; 28, 2; 32, 1; 36, 2; 40, 5; 48, 2; 52, 3; 56, 2; 64, 4.

The outstanding observation was that the effects of pregnancy persist for months after delivery, although the cervix may clinically appear normal. Secondly, biopsies from erosions often resemble normal (involuting) tissue. To demonstrate this, the changes of pregnancy are tabulated—for example, if the glands are still “pregnant” they are numerous to the extent of resembling a cross-section of a honeycomb, or if the stroma is still pregnant it is cellular or lacks intercellular substance.

Definitions

1. (a) *Glands +++*: Numerous glands up to a “honeycomb” effect. Columnar epithelium usually tall, actively secreting mucus (Fig. 2, B). (b) *Glands absent*: Either the

FIG. 2.—(A) Normal stroma. (B) Residual pregnancy-effects six weeks after delivery. Pregnancy causes the mucous glands to proliferate, while the stroma is converted to a cellular structure. Lymphocytes and plasma cells are common in the stroma of pregnancy.

FIG. 3.—Erosion six weeks after delivery—classified histologically as non-inflammatory—that is, the erosion amounted to an area of columnar epithelium on the portio. Round-cell infiltration of the stroma at the squamo-columnar junction is so common a finding that it can be taken as normal. The rest of the section was practically free from round cells.

glands were not reached or in the squamo-columnar area no glands were present at the limits of the punch. (Biopsy about 3 mm. deep.)

2. (a) *Stroma cellular*: Connective-tissue cells packed together or separated by oedema; scanty intercellular fibrils (Fig. 2, B). (b) *Hyaline*: Relatively acellular connective tissue; up to a year or more after delivery delicate intercellular fibrils predominate. (As involution proceeds this tissue spreads towards the glands from below the squamous epithelium.)

3. *Inflammation*: Inflammatory processes were seldom more than mild, and amounted to no more than stromal infiltration by round cells. Desquamation was rarely seen.

(a) *No inflammation*: Subepithelial infiltration by lymphocytes confined to a small clump around the squamo-columnar junction (Fig. 3). (b) *Mild round-cell inflammation*: Lymphocytes and sometimes plasma cells infiltrating the subsquamous and periglandular stroma (Fig. 4). (c) *Subacute inflammation*: Dilated capillaries with polymorphs, lymphocytes, and plasma cells in the stroma deep to the mucous and squamous epithelium (Fig. 5).

FIG. 4.—Squamo-columnar biopsy of normal cervix six weeks post partum. Marked round-cell infiltration of stroma, especially near mucous glands; classified in the text as “mild round-cell infiltration.”

FIG. 5.—Squamo-columnar junction of an erosion six weeks after delivery. Subacute inflammation with capillaries (arrow) packed with polymorphs and lymphocytes. Subacute inflammation is rare in erosions and controls.

Histology Six Weeks After Delivery (Fig. 6)

	Erosion	Control
1. Mucous glands:		
Numerous secreting ..	66 (89%)	37 (58%)
Inactive or few ..	1 (1.5%)	9 (14%)
No glands ..	7 (9.5%)	18 (28%)
2. Stroma:		
Cellular (still "pregnant") ..	61 (82%)	32 (53%)
Hyaline (delicate fibrils) ..	11 (15%)	18 (30%)
Adult or whorled ..	2 (3%)	10 (17%)
3. Inflammation		
None ..	26 (35%)	38 (65%)
Mild round-cell infiltration (only at the surface in tips of folds of columnar epithelium; 9) ..	35 (47%)	16 (26%)
Subacute (only at the surface in tips of folds of columnar epithelium; 3) ..	13 (18%)	5 (9%)

Fig. 6.—Gland activity of pregnant type was common to erosions and controls, but in the controls the biopsy failed to reach the glands in 18 cases and showed a few in 9 (total 42%). In erosions the stroma tends to be more cellular than in controls.

Six weeks after delivery, therefore, squamo-columnar biopsies from normal cervixes resemble those from the edge of post-natal erosions. Both show persistent pregnancy effects such as a massive gland pattern with apparently active secretion; in both, the stroma is cellular, while inflammatory reactions such as infiltration of round cells and dilated capillaries are common. It is important to note that inflammation is confined to the surface of the cervix and is generally of mild type without desquamation (Figs. 3 and 4).*

Miscellaneous Findings.—Less common pregnancy effects were also observed, such as metaplasia, phagocytosis of hyaline tissue by fibroblasts, "Hofbauer" cysts, and so on (Hofbauer, 1933). Stromal oedema, sometimes with effusion of red cells, was common in six-weeks specimens, but decidual cells as described by Sheets (1948) and McIlrath and Hellestrand (1947) were not observed. Hyperplastic cells in the deeper layers of the squamous epithelium were also occasionally seen, but there was nothing resembling intra-epithelial cancer (Danforth, 1950).

Advancing Involution

Seventy-seven squamo-columnar biopsies from both healed and persistent erosions were taken at intervals up to a year after delivery. By contrasting them with 142 specimens obtained six weeks after delivery it was possible to observe the slow process of involution as it affects mucous

*Robert Meyer's (1910) dictum, "Ohne Entzündung keine Erosion," might place most of this group among the congenital non-inflammatory types of erosion.

glands, stroma, resolution of inflammatory reaction, and so on. Secondly, biopsies from the squamo-columnar edge of persistent erosions were compared with biopsies from healed cervixes.

The outstanding change in the cervix with the passage of five to six months is in the stroma, which gradually changes from its "pregnant" or cellular state to a more fibrous or acellular structure (Fig. 7). The cellular stroma first disappears in the lower cervix beneath the squamous epithelium of the portio, but tends to persist around mucous glands or near small foci of inflammation. Soon after delivery the pregnant close-packed cellular stroma is replaced by young fibrous tissue with delicate fibrils of intercellular substance. This new fibrous tissue gives way to connective tissue possessing coarser intercellular substance. But in our sections, taken up to 12 months after delivery, the non-pregnant acellular stroma was seldom completely reproduced (compare Figs. 2A and 7).

Three to four months after delivery oedema of the stroma disappears, while the widely dilated and numerous capillaries in the stroma also disappear.

Inflammatory cells tend to become less prominent, but even months after delivery scattered foci or diffuse areas of round cells are still common (Fig. 8). By six or seven months the mucous glands become less numerous, and our biopsies often failed to reach gland tissue—that is, the mucous glands not only diminish in number but appear to retract from the lower cervix.

Fig. 8.—The effects of involution of cervical erosion (40 cases) at 20 weeks are present in the cervix with or without an erosion—namely, the glands become less prominent, the stroma loses its cellularity, while inflammation diminishes.

Fig. 7.—Persistent erosion 12 months post partum. Replacement of cellular stroma (C) by more acellular tissue (S) is not yet complete. Note the cystic appearance of the squamous epithelium.

By taking a sample of 20 specimens from persistent erosions and 20 erosions which had healed spontaneously, it is easy to show that the changes of involution affect not only erosions which persist but also those which show clinical healing (Fig. 8). Thus if a pathologist could be persuaded to give his opinion on one of our small biopsies he would have great difficulty in deciding if the specimen came from the squamo-columnar edge of a normal cervix or from an unhealed erosion. In both there would be evidence of advancing involution affecting glands, stroma, and inflammatory cells.

Non-treatment of Post-partum Erosions

Bourne and Bond (1939-40) found it difficult to correlate cervixes amputated for (clinical) chronic cervicitis with the histology, which often appeared to show no more than mild surface inflammation. Fluhmann (1948), on the other hand, in an important study of the histology of the erosions of pregnancy refers to the clinical condition as the "so-called erosion" of pregnancy. Nevertheless, in many clinics post-natal erosions are diagnosed as pathological six weeks after delivery, and routine cauterization is carried out. Two obvious criticisms of non-treatment of erosions might be made—namely, that post-natal erosions might be a source of discharge, and, secondly, they might lead to future sterility.

It has already been mentioned that few of our untreated cases of erosion were subject to mucous discharge of cervical origin; in fact, of the total of 77 cases only 4 (5%) finally had true "mucorrhoea" from erosions of the cervix. It is not suggested, however, that in non-pregnant women erosions never cause leucorrhoea; for, either by repeated Cusco examination in out-patients or by a tampon test, it is occasionally possible to prove that a patient's discharge arises in the cervix. It seems clear to us from this clinical study, however, that the cervical mucus of the post-partum cervical erosion seldom reaches the vulva in amounts to cause leucorrhoea.

Secondly, our observations on the 28 cases of persistent erosion do not suggest that sterility from impenetrable cervical mucus results from non-treatment. In fact, clear or acellular mucus is commonly secreted from large post-natal erosions, persisting for months after delivery, as in the following case:

A married woman aged 22. On three occasions endocervical spermatozoa were obtained in smears of translucent endocervical mucus. The patient had not been instructed to have coitus before presenting herself for examination. Eight months after delivery she was pregnant, still with a large erosion.

Four other women with persistent erosions became pregnant and continued to have erosions in early pregnancy, so that it appears unlikely that the untreated and persistent erosions provide a barrier to further conception.

Although it is known that pregnancy predisposes to cervical cancer (Ministry of Health Reports, 1927), the relation of post-natal erosions to the future development of cancer is unknown, and there is no evidence to show that cautery of the cervix as practised in the out-patient department with a "nasal-wire" cautery (as opposed to thermal destruction of the lower cervix) (Cashman, 1941, 1945) can prevent cancer. In fact, only a few millimetres of mucous epithelium are burned by the cautery in out-patients and are replaced by squamous epithelium. The majority of our young patients, however, will be pregnant several times in the ensuing years, and on each occasion, so to speak, they will grow a new cervix with or without an erosion—that is, in the antenatal and post-natal period the cervix will undergo a complete metamorphosis. In the light of these changes in the physiology of the cervix it is difficult to regard surface cautery of the post-natal cervix as being able to influence the future behaviour of the epithelial tissue of the cervix.

Conclusions and Summary

It seems clear to us from this clinical study that post-partum cervical mucus, possibly owing to its tenacious quality, seldom reaches the vulva in amounts to cause leucorrhoea. Post-natal erosions are, in fact, innocuous, and, although it is possible in a few cases to prove that vaginal discharge arises from them, in most cases the cervix is not the source. Treatment should therefore be reserved for persistent erosions proved to be the cause of "mucorrhoea."

Post-natal erosions usually resolve without treatment.

Post-natal erosions as well as normal post-natal cervixes can occasionally be shown to cause "mucorrhoea" six weeks after delivery.

Persistent erosions are usually innocuous, but excessive mucous discharge may demand treatment by cautery (5%).

Post-natal erosions do not cause backache.

Squamo-columnar biopsies from normal cervixes and from erosions show post-partum involution; biopsies from the edge of healed or persistent erosions are similar; both depict advancing involution.

Post-natal erosions are physiological, and cauterization is seldom indicated.

I wish to acknowledge gratefully the help I have received from my colleagues on the staff of the Birmingham Maternity Hospital, and especially Dame Hilda Lloyd, Mr. Charles D. Read, and Professor S. Zuckerman for their criticism and advice. I also wish to thank our unit sister, Miss M. Scott-Will, and senior technician, Miss M. E. Attwood, for their enthusiasm and help in conducting this investigation.

In Korea, the Assistant Director of Medical Services of the Commonwealth Division, Colonel G. Anderton, told a *Daily Telegraph* Special Correspondent (January 29), the health of the troops could not be better. Sickness rates in the summer were well below what was expected, and now the incidence of sickness and cold injuries was lower than in any other campaign. Manchurian fever, however, was still causing anxiety. Since July there have been 70 cases in the division; 16 were reported last month, but the incidence was decreasing with the colder weather. The death rate was between 7% and 10%. Work was being carried out on the disease, but so far the organism had not been isolated. All cases in the division are referred to the American hospital at Seoul, where the experiments are being done, and tons of poison have recently been distributed in a drive against rats and mice, which are suspected of carrying the infection.

CORRECTION OF E.S.R. IN ANAEMIA EXPERIMENTAL STUDY BASED ON INTERCHANGE OF CELLS AND PLASMA BETWEEN NORMAL AND ANAEMIC SUBJECTS

BY

J. C. F. POOLE, B.M.

AND

G. A. C. SUMMERS, M.B., B.Sc.

*(From the Division of Laboratories, Radcliffe Infirmary,
Oxford)*

When red cells are mixed with their own plasma in varying proportions the sedimentation rate of the more dilute suspensions is greater than that of the more concentrated ones. This observation was first made by Fåhræus (1921), and has often been repeated. On the basis of such observations, attempts have been made to allow for the effects of anaemia on the erythrocyte sedimentation rate (E.S.R.) by various correction charts and factors. Among these may be mentioned the correction charts of Gram (1928, 1929) and of Rourke and Ernstone (1930), which were based on experimental dilution of the blood of anaemic patients. The correction chart of Wintrobe and Landsberg (1935) has gained considerable popularity; a slide-rule method for correction based on this chart has even been devised (Best, 1950). The Wintrobe and Landsberg chart is based on dilution experiments with normal blood.

Any such correction chart is valid only if we assume that the E.S.R. is determined by certain properties of the plasma and by the concentration of red cells suspended in it, but not by the shape, size, specific gravity, or any other property of the cells: in other words, it is assumed that any sample of red cells suspended in a given plasma at a given concentration would show the same sedimentation rate. This assumption does not appear justified, and Hynes and Whitby (1938) have shown how Wintrobe's correction chart must be modified to fit in with observed facts. For example, in many cases of anaemia a much slower rate is found than would be expected when normal blood is diluted to a level equivalent to that of the anaemic haematocrit reading. Bönniger and Hermann (1923) noted this effect in chlorosis, and it seems to be particularly marked in sickle-cell anaemia (Bunting, 1939, and other workers). Westergren (1924) states that he has often found the E.S.R. lower than he would have expected from the reduced haemoglobin level. On the other hand, Newham and Martin (1928) maintained that the size and specific gravity of the cells do not affect the E.S.R., and this has been accepted by Wintrobe and Landsberg (1935) and restated by Cutler, Park, and Herr (1938).

Some authors have even gone so far as to deny that the number of red cells present influences the sedimentation rate: Fåhræus (1929), observing this slowing effect, believed that some compensatory mechanism was at work in anaemia. Bouton (1938), on finding that the red-cell count and the E.S.R. can fluctuate independently in the course of a disease, dismissed the idea that the red cells could have any important effect on the E.S.R. Cutler, Park, and Herr (1938) made a careful study of the formation of red-cell aggregates, interchanging cells and plasma between normal and anaemic subjects, and

concluded that it was only the plasma which influenced the rate: however, they did not use cell-plasma mixtures of equal haematocrit level, and therefore the value of their experimental results is reduced.

Terry (1950) found no significant difference between the sedimentation rates of a group of normal subjects and a group of patients suffering from anaemia "of a benign origin." He does not explain clearly how anaemia of a benign origin is differentiated from other types of anaemia, nor what precautions were taken to avoid bias against including in his benign category any patient with a markedly raised E.S.R. But whatever criteria were used, this is not an unselected series, and a statistical analysis does not improve its significance. It is one thing to say that in many cases of anaemia some compensating factor is at work which masks the potential accelerating effect of dilution—this is undoubtedly true; it is quite another matter to postulate that this compensating factor quantitatively neutralizes the effect of dilution and that therefore a raised E.S.R. has the same significance in an anaemic as in a non-anaemic patient.

In this investigation we have attempted to throw further light on the problem by studying the separate effects on sedimentation of the cell and plasma components of normal and anaemic blood.

Method

Thirty experiments have been performed with the blood of patients suffering from different types of anaemia classified under the four headings of: symptomatic (that is complicating some other disease), post-haemorrhagic, iron-deficiency, and macrocytic anaemias. Blood films were examined with special reference to red-cell size and shape. In each case information was obtained about any abnormality which might influence the E.S.R. The Westergren technique was used in every experiment. Blood was diluted with 3.8% sodium citrate in the proportion of four parts of blood to one part of sodium citrate solution. A column of citrated blood 200 mm. high was set up in a Westergren tube and the E.S.R. read at the end of one hour.

Dilutions were made according to a standardized procedure to cover a haematocrit range of from approximately 40 down to below 10. Haematocrits were always checked in Wintrobe tubes on the blood run out of the E.S.R. tube after reading. When mixtures were made, the cells, after centrifuging and removal of plasma, were washed three times by centrifuging after shaking up thoroughly with normal saline. Five to seven different dilutions were prepared with (1) normal cells in normal plasma; (2) anaemic cells in anaemic plasma; (3) normal cells in anaemic plasma; and (4) anaemic cells in normal plasma. When cells and plasma are interchanged in this way between two samples of normal blood no significant alteration in sedimentation rate is found. This observation rules out a number of possible experimental artifacts: in particular, it is evident that centrifuging and washing cells as we have done does not alter their sedimenting properties. The blood of the normal subject in each case belonged, of course, to the same ABO blood group as the patient.

Recording of Results

Graphs were drawn of E.S.R. against haematocrit for each experiment, and typical examples of the results obtained in the four principal categories of anaemia are given in Figs. 1, 2, 3, and 4. In all the graphs reproduced the haematocrit figure is the figure given by the diluted blood. The results do not seem to vary very widely from a similar dilution series made with dry oxalate anticoagulant (Hambleton and Christianson, 1939), and closely comparable series of figures

can be obtained with dry sodium citrate and with 3.8% sodium citrate solution, the sedimentation rates always being slower with the citrate solution to about the same extent at each haematocrit level (Westergren, 1924). Nevertheless, these results should be applied only to E.S.R.s determined by the Westergren method.

FIG. 1.—Symptomatic anaemia (carcinoma). E.S.R. plotted against haematocrit for: normal cells in normal plasma (N in N); anaemic cells in anaemic plasma (A in A); normal cells in anaemic plasma (N in A); anaemic cells in normal plasma (A in N).

FIG. 2.—Post-haemorrhagic anaemia (haematemesis). See legend to Fig. 1.

FIG. 3.—Iron-deficiency anaemia (menorrhagia). See legend to Fig. 1.

FIG. 4.—Macrocytic anaemia (pernicious anaemia). See legend to Fig. 1.

Fig. 5 is a composite graph showing the E.S.R. at different haematocrit levels for 34 normal blood samples. This graph therefore shows the approximate range to be expected of normal cells in normal plasma at the haematocrits given by the different dilutions, and it can be used for rough computation of the expected degree to which the E.S.R. should be

FIG. 5.—Composite graph showing E.S.R. at different haematocrit levels for 34 normal blood samples.

raised by anaemia. In order to show the approximate degree to which the different factors in the cells and plasma affect one another in the interchanges used in the experiments, the E.S.R.s were read off the graphs at the arbitrary haematocrit level of 20. The figures so obtained from the four haematocrit/E.S.R. curves drawn in each experiment indicate the effect of the plasma and of the cells upon the sedimentation rate.

Results

In describing the results of these experiments it is convenient to speak of the cells of a particular patient as having a "cell retarding factor" if they sediment more slowly in a given plasma than do normal cells, or a "cell accelerating factor" if they sediment more rapidly. Similarly, plasma may be said to have a "plasma retarding factor" if cells suspended in it sediment more slowly than they do in normal plasma, or a "plasma accelerating factor" if they sediment more rapidly. It is emphasized that these factors are postulated for convenience only and that no attempt was made to demonstrate their physical basis: indeed, this conception of accelerating or retarding factors breaks down when we consider the behaviour of blood in the macrocytic anaemias.

The accompanying Table shows cell and plasma accelerating and retarding factors for 30 cases of anaemia classified into the four groups shown. The mean values for these factors are given for each group, and, in parentheses, the lowest and highest figures obtained in each group. Accelerating factors are indicated by a plus sign, and retarding factors by a minus sign. The figures are obtained from

	Symptomatic Anaemias (14 Cases)	Post-haemorrhagic Anaemias (5 Cases)	Iron-deficiency Anaemias (6 Cases)	Macrocytic Anaemias (5 Cases)
Cell accelerating or retarding factors:				
In anaemic plasma	-17 (-86 to +5)	-6 (-14 to +3)	-11 (-31 to +2)	+27 (0 to +95)
In normal plasma	-7 (-15 to +5)	-8 (-14 to +8)	-7 (-12 to -3)	+7 (-2 to +24)
Plasma accelerating or retarding factors:				
With anaemic cells	+57 (+17 to +138)	-1 (-13 to +7)	+8 (+4 to +13)	+20 (-8 to +69)
With normal cells	+67 (+25 to +134)	-2 (-8 to +10)	+12 (+4 to +24)	0 (-13 to +17)

the graphs at the arbitrary haematocrit level of 20. For example, the cell accelerating or cell retarding factor in anaemic plasma is found by subtracting the figure for the sedimentation rate of normal cells in anaemic plasma from that for anaemic cells in anaemic plasma at the 20% haematocrit level (see Fig. 1).

From the table it will be seen that in the symptomatic anaemias a marked plasma accelerating factor and a much smaller, inconstant, cell retarding factor are found. In the post-haemorrhagic anaemias the differences are less than in the other groups, although a cell retarding factor is usually found: in fact, the blood of a patient with a post-haemorrhagic anaemia behaves much more like a dilution of normal cells in normal plasma than does any other type of anaemic blood. The iron-deficiency anaemias are characterized by a cell retarding factor and a plasma accelerating factor of approximately equal degree. In some cases the cell retarding factor predominated, giving an E.S.R. lower than would be expected from a dilution of normal cells in normal plasma to an equivalent haematocrit level.

In pernicious anaemia the position is more complicated. In all other types of anaemia it seems that if, for example, cells possess a cell retarding factor they will exhibit this property both in the normal and in the anaemic plasma; equally, if plasma is found to possess a plasma accelerating factor it will usually exert this effect both on normal and on anaemic cells. Such uniformity is not found in pernicious anaemia. Generally speaking, the cells seem to possess an accelerating factor, but this property is always more marked in the anaemic plasma than in normal plasma, and in some cases the effect is reversed—that is to say, the anaemic cells sediment more rapidly than normal cells in anaemic plasma, but more slowly in normal plasma.

Discussion

Attempts to correct the E.S.R. for the effects of anaemia are designed to assist in solving a common practical problem: an anaemic patient is found to have a raised E.S.R.—is this due solely to the anaemia, or does it suggest underlying organic disease? The authors of correction charts believe that they can answer this question, at least in the majority of cases. All correction charts are based on the assumption that abnormalities of the cells exert at most a negligible influence on the sedimentation rate. Previous workers have cast doubts on the validity of this assumption, and we believe that our experiments show conclusively that it cannot be maintained. In fact, cell factors operate in most cases of anaemia, and are often of the same order of magnitude as the plasma factors. This being so, the "corrected" E.S.R. may often be misleading to the clinician.

The nature of the cell retarding factor found in most cases of anaemia is not clearly brought out by our experimental results. It is easy to imagine that anisocytosis might interfere with rouleau formation. In all cases, apart from the macrocytic anaemias, the extent of anisocytosis as judged from the appearance of the film did seem to bear at any rate a rough relation to the magnitude of the cell retarding factor. However, this is by no means true of the macrocytic anaemias, in which marked anisocytosis may be accompanied by a cell accelerating factor. It may be that some complicating factor masks the potential effect of anisocytosis in these cases. The alternative suggestion that the relative specific gravity of the cells is the important factor cannot be ruled out: this possibility was raised by

Bendien, Neuberg, and Snapper (1932) and by Ham and Curtis (1938) on the basis of a few experiments. From our comparatively small number of observations it would be unwise to infer that any one property of the erythrocytes is responsible for the accelerating or retarding factors we describe.

A limited amount of information may be obtained from consideration of the E.S.R. and the haematocrit in conjunction with a chart like that given by Hynes and Whitby (1938) showing the sedimentation rates obtained at varying dilutions of normal cells in their own plasma, with curves lying above these limits representing degrees of elevation of the E.S.R. The basis of such a chart is given in Fig. 5. If the value found in a particular case lies well above the normal range the patient probably has some organic disease apart from his anaemia. If the reading is within the normal range or below it no definite conclusions can be drawn. While useful information could no doubt often be obtained by carrying out exchange experiments of the type we describe, the method seems altogether too time-consuming in relation to the value of the results.

Summary

The problem of the erythrocyte sedimentation rate in anaemia has been studied experimentally by interchanging erythrocytes and plasma of normal and anaemic subjects: the E.S.R. was determined at varying haematocrit levels for both types of blood, each type of erythrocyte being suspended in both types of plasma. The results of each experiment were recorded graphically.

In the symptomatic anaemias the anaemic cells sedimented rather more slowly than did normal cells both in normal and in anaemic plasma. Both types of cells sedimented much more rapidly in the anaemic plasma than in the normal plasma. Thus the anaemic cells have a slight retarding influence on sedimentation and the anaemic plasma a marked accelerating influence.

Post-haemorrhagic anaemias behaved more like dilutions of normal cells in normal plasma than did other types of anaemia, but some retarding effect of the cells was usually present.

Iron-deficiency anaemias showed a retarding influence due to the cells and an accelerating effect of the plasma of approximately the same magnitude; in some cases the retarding effect of the cells predominated, giving an E.S.R. lower than would be expected for a dilution of normal cells in normal plasma to the same haematocrit level.

In macrocytic anaemias the sedimenting properties of the cells showed marked differences according to the type of plasma. If uncomplicated, such anaemias did not usually give an E.S.R. greatly above that expected for an equivalent dilution of normal cells in normal plasma.

It may be tentatively inferred that the cell retarding effect is associated with anisocytosis.

The usefulness of methods of "correcting" the E.S.R. for the effects of anaemia is criticized in the light of

these experimental results. Some information can be gained by using a chart of the Hynes-Whitby type.

Our thanks are due to Dr. A. H. T. Robb-Smith, Director of Pathology, Radcliffe Infirmary, Oxford; to Dr. R. G. Macfarlane, in whose department this investigation was carried out, for suggesting the problem; to Dr. Macfarlane and Dr. Rosemary Biggs for constant advice and encouragement during the experiments; to Dr. O. G. Dodge for help in some of the experimental work; and to the donors of our normal blood specimens.

CORTISONE IN IDIOPATHIC STEATORRHOEA

BY

J. BADENOCH, B.M., M.R.C.P.

(From the Nuffield Department of Clinical Medicine,
Radcliffe Infirmary, Oxford)

Taylor, Comfort, Wollaege, and Power (1951) have reported favourable results in the treatment of idiopathic steatorrhoea with cortisone in doses of 25–100 mg. daily. Following the administration of the drug, there was subjective improvement, with increased appetite, a rise in the level of plasma proteins and prothrombin, and a significant decrease in the amount of fat and nitrogen excreted in the faeces. There is little evidence of impaired adrenal function in the sprue syndrome, but it is well known that cortisone in this dosage may not be acting as adrenal replacement therapy, and that improvement may occur in a number of conditions in the absence of adrenal insufficiency. We therefore decided to attempt to confirm the results of the Mayo Clinic group.

Remissions are common in idiopathic steatorrhoea, and only patients in whom the clinical condition appeared stable were chosen for trial with cortisone. We selected two untreated patients who had been under observation in hospital, and two others in whom considerable improvement had already occurred after a prolonged period of treatment with diet and vitamins, including folic acid. We felt that if the cortisone had any specific effect on the metabolic defect in steatorrhoea it should produce further improvement in the treated cases and perhaps abolish the steatorrhoea. With established methods of treatment the absorption of fat remains impaired in the great majority of patients.

Method

Each patient was given a diet containing 70 g. of protein and 70 g. of fat daily. The total amount of fat excreted in the stools during three consecutive periods of four days,

separated by carmine markers, was estimated by the method of van de Kamer, ten Bokkel Huinink, and Weyers (1949). One patient who had also been the subject of a calcium balance had a control period of 36 days. At the end of the control period each patient was given 100 mg. of cortisone daily by intramuscular injection for 24 to 28 days, followed by a smaller dose for two to three days before the drug was discontinued.

During the last two weeks of treatment with cortisone a second fat balance was carried out, and the results were compared with those obtained during the control period. In each case the excretion of nitrogen in the faeces was estimated during the period of control, and again during the second fat balance while the patient was receiving cortisone. A radiograph of the chest was taken before treatment was started, and changes in weight, blood pressure, and serum electrolytes were recorded during the trial. Three of the patients, Nos. 1, 2, and 3, were allowed to go home between the two balances, but all were admitted to hospital during the periods of collection of faeces.

Results

Both the patients who had had previous treatment felt better, and in one the bowels were opened less frequently and the stools became more formed. In one of the untreated cases (No. 4) there was a great improvement in appetite and morale, although little change occurred in the action of the bowels. In the other (No. 3) there was no subjective improvement, but the diarrhoea decreased. One patient (No. 2) gained 2.4 kg. in weight during the period of treatment, owing to the retention of fluid.

Excretion of Fat and Nitrogen.—The Chart shows the percentage of dietary fat excreted in the faeces and the amount of faecal nitrogen in each period of four days, before and during treatment with cortisone. The great variation in the results of consecutive estimations in Case 4 was due to irregular bowel action, which made separation of the periods difficult. The Table gives the difference between

Excretion of Fat and Nitrogen in the Faeces Before and During Treatment with Cortisone

Case No.	Mean % Dietary Fat Excreted During Consecutive Periods of 4 Days. (Number of Periods in Parentheses)		Mean 4-day Excretion of Nitrogen in Faeces (g.)		Length of Treatment (Days)	Total Dosage of Cortisone (g.)	
	Before Treatment With Cortisone	During Treatment With Cortisone	Before Treatment With Cortisone	During Treatment With Cortisone			
Previously Treated	1	16.7 (3)	12.0 (3)	7.4	5.2	28	2.80
	2	16.5 (3)	11.1 (3)	6.9	6.9	33	2.88
Previously Untreated	3	43.6 (3)	29.5 (2)	11.1	11.9	31	2.89
	4	25.0 (9)	23.0 (3)	5.6	9.9	28	2.55

For fat excretion: $t = 2.49$; $p > 0.05$.

the mean four-day excretion of dietary fat before and during treatment with cortisone. The difference between the amounts of fat excreted is not significant. The effect on the excretion of nitrogen was variable.

Discussion

Hypotension, pigmentation of the skin, and asthenia are common in patients suffering from steatorrhoea, and several observers, noting the close resemblance to Addison's disease, have suggested that adrenal insufficiency may play some part in the pathogenesis of the sprue syndrome (Gloor, 1930; Thaysen, 1932). However, in spite of the fact that the hormones of the adrenal cortex exert an influence on the

normal process of fat absorption (Bavetta, Hallman, Deuel, and Greeley, 1941; Frazer, 1946), and that an excessive quantity of fat is present in the faeces of some patients with Addison's disease (Bergner, Lewis, Stout, Thorn, and Emerson, 1948), the evidence of adrenal insufficiency in sprue or idiopathic steatorrhoea is slight. Black (1946) showed that the hypotension and asthenia in sprue was not accompanied by an increase in serum potassium or a failure of the kidney to conserve sodium, as might be expected in adrenal failure, and cases of steatorrhoea have been treated with deoxycortone (Leishman, 1945) and corticotrophin (Frazer, 1949) without improvement.

The response to cortisone was not striking, which is in keeping with the belief that adrenal cortical function is normal in cases of steatorrhoea. Each patient improved, but results based on the mean four-day excretion of fat can be quite variable and must be interpreted with caution (Fourman, Higgins, Quelch, O'Brien, and Witts, 1948). Taylor, Comfort, Wollaeger, and Power (1951) found more improvement, but the difference may depend on the selection of patients. In patients suffering from intractable diarrhoea cortisone might prove of greater benefit, for Almy (1951) has reported a severe case in which the diarrhoea and hypoproteinaemia responded to treatment with adrenocorticotrophic hormone when other forms of treatment had failed.

Summary

Four patients with idiopathic steatorrhoea, two of them previously untreated, were given 100 mg. of cortisone daily by intramuscular injection for four weeks.

Although the excretion of fat decreased in all, the difference was not statistically significant, and in none was the steatorrhoea abolished.

I wish to thank Miss Moira Aitken and Miss Beryl Brinkhurst for their assistance in the biochemical investigation, Dr. A. M. Cooke for permission to include one patient who was admitted

under his care, and Professor L. J. Witts for his advice and criticism at all times. I am grateful for the kindness of Dr. Wollaeger and his colleagues, who made their results known to us prior to publication.

A recent letter in *Country Life* has the title "Causes of Death in 1711," and gives an account of how a list of old christenings and burials, with causes of death, was found pasted inside the door of a William and Mary marquetry long-case clock. The list refers to London only, and is taken from the reports of the various parish clerks. It covers the year December 12, 1710, to December 11, 1711, during which it records 14,706 christenings and 18,874 burials. Some of the diagnoses of deaths are probably fairly reliable—for example, smallpox 915, death in childhood 195, and perhaps "stoppage in the stomach" 255, rickets 196, and "jandies" (jaundice) 51. But "cancer" is given as only 75, and presumably means externally visible tumours, whether malignant or not, while "rheumatism" numbers 9 and scurvy 2, and the label in these cases is obscure and probably misleading. Some of the causes of death sound very odd to the modern ear. Such are Grief (9), Gripping in the Guts (614), Lethargy (7), Melancholy (1), Surfeit (61), and Teeth (1,013).

(130 γ in precipitate; 20 γ in filtrate). After 12 days' treatment the urine contained 28 γ per 100 ml. Eleven days later the mercury in the urine was 20 γ per 100 ml., and a fortnight later it was 8 γ . The child made an uninterrupted recovery. Other biochemical investigations are shown in Table II.

Case 3

Ten days before the admission to hospital of a boy aged 11 months the mother noticed that his eyelids were swollen in the morning. Four days later the feet and ankles began to swell, and in a few days the abdomen became swollen. The child was admitted to hospital on July 20, 1951. There had been no diarrhoea or vomiting. On examination there was generalized oedema, and the urine contained albumin (+ + +) (Esbach, 14 g./litre). Hyaline and granular casts were present and there were more than 50 red cells in the centrifuged deposit. On admission no inquiry had been made about mercury. On recalling the parents it was found that the child had been given one teething powder on alternate days for the past five months. These powders each contained approximately 0.64 gr. (42 mg.) Hg in the form of calomel, so that about 3.1 g. Hg had been given in that period. Treatment with dimercaprol was started on July 28,

Chart showing the marked loss of weight which followed treatment of Case 3 with dimercaprol.

20 mg. being given intramuscularly four times daily for two days, 20 mg. twice daily for one day, and 20 mg. daily for 10 days. There was marked diuresis, and the loss of weight which occurred is shown on the Chart. Before treatment the urine contained 75 γ Hg per 100 ml. A few days after dimercaprol was started the mercury content rose to 120 γ per 100 ml. Seven days later the urine contained 28 γ Hg. Three weeks later it contained 9 γ Hg. The child was given two intravenous plasma transfusions, one during the course of treatment with dimercaprol and the second a week later. During the five days after dimercaprol was stopped the child lost about 3½ lb. (1.59 kg.) in weight and the oedema was much diminished. A few days later the oedema recurred to some extent, but a fortnight afterwards no oedema could be detected though the urine still contained some albumin (Esbach, 1 g./litre). In view of the persistent slight albuminuria and the fact that the mercury content of the urine had risen to 24 γ per 100 ml. a further course of dimercaprol was started on September 24. Two days after this course was begun the urine contained 260 γ Hg per 100 ml., and six days later 58 γ Hg. As the child had had a patch test (in which a small amount of ointment containing 13% calomel was applied to the skin for 48 hours) we felt it necessary to find out if this test had affected the amount of mercury excreted. A similar patch test (mercury content approximately 5,000 γ) was applied to a normal baby of the same age for 48 hours. This baby's urine contained no mercury before the patch test, but 24 hours after its

TABLE III.—Case 3

Date	Blood Urea mg./100 ml.	Serum Cholesterol mg./100 ml.	Serum Proteins		
			Total g. %	Alb. g. %	Glob. g. %

3/9/51 ..	28				
24/9/51 ..	24				

application the urine contained 6 γ per 100 ml. Twenty-four hours later the urine contained 2 γ . Four days later no mercury was detected, but two days later the urine contained 4 γ Hg. These tests are not strictly comparable, since the normal baby was not receiving dimercaprol. In neither case was the skin test positive. About 21 days after the second course of dimercaprol the urine became free of albumin and the child was discharged well.

Case 4

Two weeks before his admission to hospital the mother of a boy aged 12 months noticed that his eyelids were swollen. Two days before admission the abdomen, penis, and legs became swollen. For a week little urine had been passed and there was marked thirst. There had been no diarrhoea. The child was admitted on September 14, 1951. On examination there was generalized oedema and the urine contained albumin (+ +). Scanty hyaline casts were present and a few red cells. This child had been given one teething powder on alternate days for the past six months. These powders each contained approximately 0.64 gr. (42 mg.) Hg in the form of calomel—i.e., approximately 3.8 g. Hg had been taken in six months. On September 20 the urine contained 52 γ Hg per 100 ml. No dimercaprol was given in this case. On admission the child's weight was 26 lb. 14 oz. (12.2 kg.). The oedema decreased rapidly, and in the course of 10 days cleared completely. On October 4 his weight was 20 lb. 12 oz. (9.4 kg.). A week later the weight was 19 lb. 12 oz. (9 kg.), and the general condition was greatly improved. Nine days later vomiting and diarrhoea occurred for a few days. On October 24 the urine contained 44 γ Hg per 100 ml. Microscopy of urine was negative and no albumin was present. The infant was discharged well on October 25 and without any renal abnormality. He has since remained well. Other biochemical investigations are shown in Table IV.

Case 5

We are indebted to a colleague for the following case history.

A child aged 19 months was admitted to hospital with generalized oedema which had been present for three days and with marked albuminuria. Despite routine treatment for a month the oedema and albuminuria persisted unabated. At this point the possibility of a mercury nephrosis was raised, and an interview with the parents uncovered the fact that one teething powder had been given daily for three to four months before admission. Each powder contained approximately 0.56 gr. (36 mg.) Hg. Urine for mercury estimation, obtained with difficulty, was found to contain 22 γ Hg per 100 ml. Unfortunately the child deteriorated rapidly and died before treatment with dimercaprol could be started. Permission for necropsy was refused. We believe that this was a case of mercury nephrosis.

The method used for the mercury estimations was essentially that of Milton and Hoskins (1947). The mercury content of the urines of 12 normal children was estimated by the same method for use as controls. In nine of these no mercury was found in the urine. One had 1 γ Hg per 100 ml. of urine and the other two had 3 γ Hg.

Discussion

The mercurial compounds given to these children are in common use, but the danger of causing nephrosis by their prolonged ingestion is not recognized. In three of the cases

no inquiry had been made about the administration of mercury compounds at the first interview with the parents, so that the possibility that mercury was the cause of the nephrosis would not have come to light had our suspicions not been previously aroused. Our experience with Case 3 shows that a considerable amount of mercury may remain in the body for long periods and that more than one course of dimercaprol may be necessary to eliminate it adequately. If the treatment with dimercaprol is instituted promptly complete recovery of renal function is possible. Case 4 shows that in some cases spontaneous recovery may occur when the intake of mercury is stopped, though its excretion may continue for relatively long periods. On the other hand, Case 5, in which no dimercaprol was given, proved fatal.

In view of these findings we urge that mercury compounds should be eliminated from all teething powders and that other mercury compounds, such as grey pills, be used with care, and prolonged administration be avoided in young children. Teething powders not containing mercury are free of the risks we have described.

Summary

Five cases of mercury nephrosis are described. Complete recovery in a short period in three cases treated with dimercaprol is reported. Of two cases not treated with dimercaprol one patient recovered and one died.

We are indebted to the resident medical and nursing staffs who have cared for these children while in hospital, to Miss J. Summerscales for assistance with the mercury estimations, and to Miss P. M. Gorse for routine biochemistry in some of the cases.

FATAL HYPOKALAEMIC ALKALOSIS WITH TETANY DURING LIQUORICE AND P.A.S. THERAPY

BY

N. J. ROUSSAK, M.B., B.Sc., M.R.C.P.

Medical Registrar, Manchester Royal Infirmary

This is a report on a patient who, while receiving treatment for tuberculous meningitis, developed unexplained electrolyte abnormalities, from which she died. Papers published subsequently have thrown light on the mechanism of her death.

Case Report

A girl aged 15 received a full course of streptomycin for miliary tuberculosis with tuberculous meningitis, and was discharged from hospital on February 24, 1950, having made a satisfactory recovery. She was seen at intervals as an out-patient, and gained weight and strength. On May 27 she was readmitted with a recurrence of the meningitis, and was treated with intramuscular and intrathecal streptomycin and sodium para-aminosalicylate (P.A.S.). The P.A.S. was given in a mixture containing 2 g. of sodium para-aminosalicylate and 12 min. (0.72 ml.) of ext. glycyrrh. liq. B.P., and the dose was increased gradually to 20 g. daily. About 595 ml. of ext. glycyrrh. liq. was taken over the whole period. The meningitic symptoms showed signs of improvement, but on August 3 she complained of stiffness of her arms and legs, and there was twitching of the face. Later in the day she was reported to have had two epileptic attacks.

There were no further attacks during the next two weeks, during which phenobarbitone was prescribed, but stiffness was still a complaint. About August 24 muscular cramps occurred, and it was plain that she was having severe tetany, with carpopedal and facial spasm, and slight respiratory difficulty. There was no evident hyperpnoea. The serum calcium was found to be low (7.5 mg. per 100 ml.), and plasma alkali reserve 82 vols. CO₂ per 100 ml. The urinary calcium was normal as judged by Sulkowitch's reagent. Repeated administration of calcium gluconate intravenously had only a transient effect on the attacks of tetany, which increased in duration, and Trousseau's sign was constantly positive. On August 27 the electrocardiogram showed ST depression as occurs in hypokalaemia. On three occasions generalized convulsions with opisthotonos occurred during severe attacks of tetany. She gradually became weaker, with rapid shallow respirations, and died on September 2. The biochemical findings on the last two days of life were those of a hypochloraemic hypokalaemic alkalosis, and are shown in the Table.

Date	Plasma CO ₂ Vols./100 ml.	Serum K mg./100 ml.	Plasma Cl mg./100 ml.	Serum Ca mg./100 ml.	Serum Na mg./100 ml.	Serum Inorganic Phosphorus mg./100 ml.
Aug. 25	82		374	7.5		
" 26	82		410			
" 28	82	13	386	8.5	345	3.7
" 30			386	8.5		
" 31	92	13	421		345	

On August 28 the serum alkaline phosphatase was 5 K.-A. units. On August 31 the serum albumin was 2.1 g.% and globulin 3 g.%.

At the post-mortem examination there was evidence of active tuberculous meningitis.

Discussion

One month after this patient had died, Borst *et al.* (1950) showed that liquorice had a deoxycortone-like action, and Strong (1951) has reported that two patients with tuberculosis who received P.A.S. flavoured with liquorice developed tetany with similar electrolyte findings to those of my patient. Also, Strong was informed by Cayley, who had recorded the development of hypokalaemia in three patients having P.A.S. (Cayley, 1950), that liquorice had also been given in his cases.

There seems to be good circumstantial evidence that liquorice was responsible for the electrolyte changes shown by these patients and the fatal case here recorded. The tetany seems to have been less severe in the cases reported by Strong than in the present case. His patients, although having cramps and positive Trousseau's sign, had a negative Chvostek's sign, but my patient had facial, carpopedal, and laryngeal spasm, with convulsions. The low serum calcium was due to the hypoalbuminaemia (2.1 g. of albumin per 100 ml.). The presence of a normal urinary calcium, as estimated by Sulkowitch's reagent, suggests that the diffusible calcium was normal in amount in the serum. Thus the tetany was unrelated to the low serum calcium.

Hypochloraemic hypokalaemic alkalosis is found in Cushing's syndrome and can be produced in man by cortisone, but the only evidence I can find of its production by D.C.A. is recent work by Seldin *et al.* (1951). These workers suggest, as a result of experiments, that D.C.A. has no direct effect on the renal excretion of potassium, but that a potassium diuresis may follow D.C.A. administration as a passive consequence of sodium retention. They were able to produce a hypochloraemic hypokalaemic alkalosis by D.C.A. if sodium was given freely, and in fact my patient was receiving the sodium salt of P.A.S., and was later given intravenous sodium chloride because of the hypochloraemia. Tetany is not mentioned by these workers, nor in reports of cortisone toxicity, and in fact the low serum potassium would make the occurrence of tetany unlikely. Tetany in

other forms of metabolic alkalosis is, of course, well recognized. The P.A.S. could hardly have produced the observed electrolyte changes, because salicylate causes a respiratory alkalosis, with low alkali reserve, but the addition of a mild respiratory alkalosis to the metabolic alkalosis caused by the liquorice would favour the occurrence of tetany.

It is understood that difficulty has been found in producing electrolyte abnormalities experimentally with some preparations of liquorice, and it is possible that there may be a variation in the D.C.A.-like activity of different batches of liquorice extract.

It is interesting that the urinary chloride concentration, estimated by the Fantus test, remained very high (4-8 g. per litre) throughout the last week, contrary to what one might expect from the combined effects of hypochloroemia, alkalosis, and D.C.A.-like liquorice. In fact, this is often found in hypokalaemia, as Fourman (1951) points out.

Summary

A patient receiving sodium *para*-aminosalicylate for tuberculous meningitis developed a metabolic alkalosis, from which she died.

Liquorice, used as a flavouring agent with the P.A.S., appears to have been responsible.

I am grateful to Dr. N. Kletts for permission to record this case. My thanks are also due to Mr. Varley for the biochemical determinations, and Dr. D. A. K. Black for helpful advice.

CASE ILLUSTRATING HAZARDS OF MANIPULATIVE TREATMENT IN LUMBO-SACRAL DISK PROTRUSIONS

BY

ROBERT HAFNER, F.R.C.S.

Orthopaedic Registrar, St. Peter's Hospital, Chertsey

A recent experience having a bearing on the practice of manipulation of the spine for lumbo-sacral disk lesions seems worth recording.

Case Report

A man aged 36 who was engaged in heavy work had a sudden onset of low-back pain spreading down the back of his right leg to the foot. There was a past history of two previous similar attacks. A radiograph of the lumbo-sacral spine showed the L5/S1 joint space to be diminished posteriorly; otherwise there was no abnormality.

The patient was suffering from a protrusion of an intervertebral disk of the lumbo-sacral spine. The physical signs did not alter during five weeks' rest in bed, although the symptoms were definitely diminished. He was encouraged to move his back under intravenous procaine analgesia (5 ml. of a 1% solution of procaine). Although only 30 degrees of flexion was allowed he suddenly experienced very severe pain down the back of his right leg, which caused him to cry out. Morphine was necessary. Flexion of the spine and raising of the straight leg were not possible. The pain continued for 48 hours, until laminectomy was performed.

At operation the cauda equina was displaced backwards by a large disk protrusion, over which the first sacral root was tightly stretched. Furthermore, deep to this, in the intervertebral space, was a considerable quantity of "sequestered" nuclear material, lying free and comprising the remainder of the nucleus pulposus. This could have been forced into the spinal canal by pressure resulting from increased movement of the spine. The operative findings are illustrated in Fig. 1; the disk material after removal is shown in Fig. 2.

Follow-up Report.—On the day after operation, February 12, 1951, the patient was free from pain but had some numbness of the right foot. He remained free from symptoms and was allowed up 17 days after operation. He was discharged to his own home on March 5, and returned on April 2 to the same heavy work that he had been doing pre-operatively. He has since been at this work, and when last seen (September 16) he was symptom-free.

FIG. 1.—Diagrammatic representation of the operative findings.

FIG. 2.—(A) The disk material lying free in the spinal canal, and (B) the disk material in the intervertebral space. Marked distances equal 1 cm. and 2 cm.

Commentary

The increased flexion of the spine forced more disk material into the spinal canal, exaggerating the symptoms and signs of lumbo-sacral root pressure. The operative findings of more "free" nuclear material lying ready to enter the spinal canal demonstrates that had more flexion been obtained, as in a forceful manipulation for instance, the size of the "tumour" in the spinal canal might well have produced a cauda-equina lesion.

Although it is not our practice to use manipulation in the treatment of lumbo-sacral disk lesions, we considered the possibility that we were dealing with an uncommon type in which the extruded disk material was nipped by the posterior margin of adjacent vertebral bodies and so prevented from returning. We wondered if the muscular relaxation and increased movement of the spine, made possible by analgesia, would result in sufficient widening of the intervertebral space to allow the prolapse to reduce spontaneously.

It is interesting to recall Goldthwait's (1911) report of a case made worse by manipulation. The following is a brief extract.

A man aged 39 developed a severe attack of "lumbago" after a fairly long car journey and carrying a heavy suitcase for over half a mile. A previous similar attack seven years before had been treated with a surgical corset and had resulted in complete recovery. After a restless night the patient got up and took a tub bath. "On trying to get out of the tub, in bending forward and straining to get up, something slipped in his back, entirely different from anything he had before experienced. The body was drawn forward and to the left; there was intense pain, so that it was with great difficulty that he was able to get back to his room, and the suffering continued until he was seen by the doctor four hours later. At that time the body was held bent forward and to the left. There was extreme tenderness in the sacral region, with pain extending into the legs, the right being worse than the left." The condition was regarded as a sacro-iliac displacement and two manipulations were given, the first under general anaesthesia and the second without an anaesthetic. A cauda-equina lesion was produced, the patient having urinary and faecal incontinence and a flaccid paraplegia.

The case stimulated Goldthwait to much thought and research, from which he concluded that intervertebral disk prolapse played a large part in the production of "lumbago," "sciatica," and cauda-equina lesions.

I wish to thank Mr. B. H. Burns and Mr. R. H. Young for their permission to publish this case, treated under their care at St. Peter's Hospital, Chertsey.

Medical Memoranda

Prostatic Obstruction and Inguinal Hernia: A New Approach

Straining at micturition and the weakening of the tissues which accompany advancing age are well-recognized factors in the aetiology of inguinal herniae. It is not surprising, therefore, that cases of prostatic obstruction are often complicated by herniae. McDonald and Huggins (1949) found the incidence to be 15%. These herniae are liable to the serious complication of strangulation, itself a more lethal malady than prostatic obstruction. It thus behoves the surgeon to cure both conditions.

Now that asepsis, stressed by me (Moore, 1939) and by Wilson Hey (1945), has been more generally observed in urology, prostatectomy has become a safe operation. Wilson Hey has already stated that it can be safely combined with other procedures, including herniorrhaphy. It has become my routine to deal with the inguinal hernia at the same time as the prostate. For this reason, when the patient has a hernia I recommend open operation, even in those types of prostatic obstruction in which I would normally carry out a transurethral procedure. For the past 12 years I have used almost entirely only the transverse suprapubic incision for operations on the prostate and bladder. Through this incision I also carry out inguinal herniorrhaphy—often on both sides.

Although many patients who present with prostatic obstruction are found on examination to be suffering from inguinal hernia, one also encounters cases of inguinal hernia in old men who make no complaint of urinary symptoms. On direct inquiry and investigation many are found to be suffering from prostatic obstruction. If the prostate is not treated they often develop post-operative retention of urine

which fails to respond to conservative measures. Eventually they have to be submitted to prostatectomy, in either one or two stages, with all the dangers of the sepsis which has developed during the interval. There is no question that the period in hospital after a one-stage operation dealing with both conditions is far shorter than that following prostatectomy performed some time after herniorrhaphy. In fact, the period in hospital after a combined prostatectomy and herniorrhaphy is no longer than that after a prostatectomy alone.

TECHNIQUE

In old bad-risk cases I always employ low spinal anaesthesia and a local block of the abdominal wall. A transverse incision 4-6 in. (10-15 cm.) long is made a finger-breadth above the pubis. If only a one-sided hernia is to be done more of the incision is placed on that side of the midline. The skin, superficial and deep fascia, and the anterior rectus sheaths are opened in the line of the incision, which extends a little lateral to the rectus into the aponeuroses of the external and internal oblique muscles on the side of the hernia. In the midline the rectus sheath is separated from the linea alba down to the pubis and up towards the umbilicus for 2-3 in. (5-7.5 cm.). The rectus muscles are then separated in the midline and the type of prostatectomy preferred is carried out. In my practice this is almost always a Millin prostatectomy.

When this procedure has been completed the retractors are removed and the muscles allowed to fall together. The inguinal canal is then approached lateral to the rectus muscle between the internal and external obliques, where they are fusing to form the rectus sheath. When these are gently separated the arching fibres of the internal oblique forming the cremasteric muscle are soon visible. These are divided in the length of the canal and the cord and its contents exposed. The sac, whether direct or indirect, is dissected free and dealt with in the ordinary way. If the canal is weak and requires strengthening, any of the usual methods can be used. When the Bassini procedure or one of its modifications is adopted it is evident that the conjoined tendon can be brought down to the inguinal ligament with much less tension than in the more direct approach, because the internal oblique has already been incised at the level of the suprapubic wound. It is important in closing the transverse incision that the upper leaves of the external and internal obliques should be sutured to the lower one of the external oblique only, otherwise the relaxation of the internal oblique already obtained is lost. During the operation I often divide the vas as near the external ring as possible, preferably on the external side. Before the wound is finally closed the cave of Retzius is usually, but not always, drained.

Post-operative Course.—Sulphadimidine, 1 g. six-hourly, and penicillin, 200,000 units intramuscularly eight-hourly, are given two days before the operation, and are continued for five days after it. In cases with urinary infection due to organisms insensitive to these agents streptomycin is sometimes used, 0.5 g. being given by intramuscular injection 12-hourly for four to five days. Normally, patients are allowed up on the second day after operation. The cave of Retzius drain is also removed on that day. The catheter is removed on the fifth day. When a hernia has been done at the same time as the prostatectomy the patient is usually kept in bed for seven days. Patients are discharged from hospital 10 to 12 days after the operation.

COMMENT

I have carried out this operation many times and have had no cause to regret it. Many of the patients have been of the poor, old, municipal-hospital type. The results of the cures of the herniae have been as good as those obtained by any method of treatment in people of this age. The patients are delighted to get rid of their ruptures at the same time as their urinary trouble; surgically they are very much safer. It may be objected that leakage of urine may lead to infection

of the inguinal canal. In modern prostatectomy, however, practically speaking, no leakage occurs. Whatever theoretical objections may be raised against the method, in practice it works.

Paralaryngeal Actinomycosis in a Child

Actinomycotic infection in childhood is a rarity. The following case is of interest in view of the mode of presentation, the early stage at which actinomycotic infection was discovered, its occurrence in a rarely encountered site of the cervico-facial region, and the peculiar eosinophilic inflammatory reaction.

CASE REPORT

The patient, a girl aged 8, attended as an out-patient under Mr. W. R. S. Hutchinson on March 4, 1950. She had had a small painless left-sided cervical swelling for the past four months, clinically diagnosed as tuberculous adenitis. There

Photomicrograph of abscess, showing felted mass of actinomycotic hyphae lying within.

was no history of any serious illness or contact with tuberculosis, and she was otherwise quite healthy. X-ray films of the chest revealed nothing abnormal, the mouth and upper respiratory passages were free from disease, and there were no carious teeth.

On April 4 she was admitted for removal of the supposed lymph nodes. At operation, performed by Mr. B. Courtice, a mass, approximately 1 by $\frac{1}{2}$ in. (2.5 by 1.9 cm.), was found in the lower half of the anterior triangle of the neck lateral to the trachea and the infrahyoid muscles deep to skin, which was not involved, and deep to the cervical fascia. It was not encapsulated. A fibrous band was found passing from the mass upwards in the neck towards the angle of the jaw.

Histological examination revealed that the mass was not of lymph nodes, but consisted of fibro-muscular tissue surrounding a small central abscess. Lying within the abscess was a discrete felted mass of actinomycotic hyphae (see illustration). The surrounding cellular reaction infiltrating the muscle around showed polymorphs, lymphocytes, and

plasma cells, with a strikingly large number of eosinophils. Numerous further sections of the tissue submitted failed to reveal any other actinomycotic masses.

Investigations into the staining reactions of the organism were limited by the minute amount of available material. It was found to be Gram-positive, non-acid-fast. An unsuccessful attempt was made to culture the organism from a slight discharge from the wound following its discovery in the abscess. The child was treated with penicillin, 500,000 units daily for three weeks. The wound healed rapidly, and so far there has been no recurrence.

COMMENT

It is suggested that the case was one of the primary paralaryngeal or parapharyngeal group of cervical actinomycosis first described by Hoffmann (1906). The situation in the neck, the absence of any external wound or history of trauma in this region, and the lack of any evidence of actinomycosis in the mouth or elsewhere in the neck all fall in with this view.

Hoffmann's first case presented sinus formation and swelling of the arytenoid cartilages; in 1909 he described a further nine cases of paralaryngeal actinomycosis and stated that laryngeal involvement was not constant. Beysiegle (1933) found in the literature 19 cases of laryngeal actinomycosis and considered that there were very few cases of actinomycosis of the neck related to the larynx without evidence of perichondritis. Vogel (1935), in a review of 14 cases, describes one case without involvement of the skin or of the larynx. Peter Childs (1948) describes a case of paralaryngeal actinomycosis without involvement of skin or larynx which he considers to be only the second to be recorded. Both Hoffmann and Vogel found paralaryngeal cases commoner on the left side, adding that lymph-node involvement was not a feature, and that there was no relation to carious teeth. Lamb, Lain, and Jones (1947) review cervico-facial actinomycosis. They mention the rarity of primary cervical cases, restricting this group to cases in which infection does not obviously spread from neighbouring mucous membrane or from systemic infection. They describe one primary case only, and in this the patient had infiltration at the base of the left lung, which may have been actinomycotic.

There are three views on the mode of entry of the fungus in the paralaryngeal group: (1) Entry through the lateral pharyngeal wall via the inferior constrictor muscle is suggested by Hoffmann; he constantly found an indurated band from the angle of the jaw to the upper end of the swelling in the neck. This band was found in my case. (2) Entry via the tonsils is suggested by Vogel. (3) Schütz (1938) concludes that infection travels directly through the mucous membrane of the pharynx or hypopharynx. The point of entry of the organism in my case is unknown.

As to why a parasitic organism becomes pathogenic, Mathieson *et al.* (1935) suggest that it results from repeated absorption of toxins, ultimately causing allergic sensitization. The very marked eosinophilic cellular reaction which was so striking a histological feature in my case may be relevant to this view.

I am grateful to Dr. S. C. Dyke and Dr. J. T. Duncan for advice. Acknowledgment is also made to Mr. W. R. S. Hutchinson for permission to publish the case.

Reviews

THE OLD AND INFIRM

Adding Life to Years. By Lord Amulree, M.D., F.R.C.P. Preface by Alderman Fred Messer. (Pp. 101; illustrated. 8s. 6d.) London: National Council of Social Service. 1951.

Administrative changes are usually advocated because it is hoped they will solve old problems; they are resisted because it is feared they may create new ones. As a rule both hopes and fears prove to be well grounded, and whether on balance changes are worth while depends, not upon their complete success, but upon whether the new problems prove to be less intractable than the old ones.

In so far as they relate to the welfare of old people, recent changes in medical and social administration run true to type, although at first sight it may appear easier to identify the problems created than the problems solved. The new problems have resulted from the division between two bodies—regional hospital boards and local authorities—of responsibility for services formerly vested in a single authority. To the patient seeking admission to a hospital for the chronic sick the loss of "admission as of right" must seem to be a serious fault for which there have as yet been no apparent compensations. But compensations there are, and Lord Amulree's brief but adequate account of the history and present status of services for the aged and chronic sick will help to put them into perspective.

Lord Amulree reminds us that the most serious deficiencies in these services are of long standing; they are rooted in the history of the Poor Law, and were discussed clearly and critically in the Minority Report of the Poor Law Commission of 1905. The remedy then suggested was a breakdown of the old unscientific category of the aged and infirm, with classification of patients and adaptation of services to their medical and social needs. This is still the remedy, and more progress has been made towards applying it in the past five years than in the previous forty. In no small part this progress has been due to the same Acts of Parliament which have created new problems by dividing responsibility between two authorities. The division of responsibility has contributed in two ways: it has given hospital boards a strong motive for classifying patients according to their needs, and it has brought into contact with hospitals for the chronic sick physicians who examine the services there provided in the light of the best standards of the voluntary hospitals. Lord Amulree is one of these, and, although his book is written against the background of a long-standing interest in the welfare of old people, it has profited from his recent experience in starting the first geriatric unit in a teaching hospital at St. Pancras.

THOMAS McKEOWN.

TEXTBOOK OF PHYSIOLOGY

A Textbook of General Physiology. By Hugh Davson, D.Sc. (Pp. 659; 288 illustrations. £2. 5s.) London: J. and A. Churchill. 1951.

Sooner or later the physiologist, pathologist, or clinician goes to the basic sciences to explain his observations and experimental results. He will analyse his work on the intact organism in terms of chemistry or physics.

Dr. Davson has addressed his book to the degree student in physiology and related subjects, to the medical student interested in physiology, and to the mammalian (including human) physiologist wanting to know the underlying fundamentals. Starting with the structural basis of living matter, he discusses the transformations of living systems. Accounts follow of the transport of water and solutes and of the characteristics of excitable tissue and the mechanism of muscle contraction. The whole ends with a section on the effect of light on, and its emission by, the organism.

The book is lucidly written and well illustrated. Those who practise the art of medicine will be pleased that their worries will be solved without undue strain on their mathematical ability. It will be essential to experimental research workers. Unfortunately, the author has not been able to find space for chapters on aqueous humour, synovial fluid, and phototropic phenomena. Two grave omissions are a full discussion of the electronic theory of valency, with its application to physiology and medicine, and discussion of the work of Lohmann and the role of high-energy bonds and the principles of measuring bond energy. Would it be too much to ask that a second edition include these subjects? Perhaps, too, that it should follow a useful American practice and include an index of names?

The book's title invites comparison with Bayliss's *Principles of General Physiology*. This is not fair; though this is a textbook by one of our younger and more brilliant physiologists, "Bayliss" was the matured vintage philosophy of a scholar and pioneer.

A. ST. G. HUGGETT.

ELATION

The Psychoanalysis of Elation. By B. D. Lewin, M.D. (Pp. 200. 15s.) London: The Hogarth Press. 1951.

Psycho-analytic contributions to the study of the psychoses have ranged from some original papers of fundamental importance to a few more ambitious treatises which, however suggestive in outline, are not yet sufficiently precise and detailed to meet the needs of the general psychiatrist. So far very few specialized studies of the great psychotic subgroups have been attempted. Dr. Lewin has broken new ground in this direction. Taking as his subject the comparatively neglected problems of elation, hypomania, and mania, he has reviewed psycho-analytic work in this field, adding a detailed account of his own views and observations on the general function of elation.

His review of the literature is in its way masterly, and both psycho-analysts and general psychiatrists should be grateful for it. The presentation of his own views unfortunately does not come up to the same high standard. It is somewhat confused, a little too dogmatic in its theoretical outline, and shows some of the faults consequent on generalizing from particulars. It also suffers from following too closely the present psycho-analytical fashion of regarding practically all mental manifestations as "defences," to the neglect of their more positive functions both individual and phylogenetic. There is certainly a good deal of "denial" in mania; there is equally certainly a marked oral element in it, just as there is in depression. But two swallows do not make a summer. Elation is in many respects a compound affect of composite origin; and it is not altogether a service to hedge-in its functions in terms of existing and somewhat sketchy hypothetical reconstructions of the reputed minds of sucklings. In particular, Dr. Lewin's correlations between hypomania and sleep are unduly restricted and hampering. Despite these criticisms his book is a valuable one, containing more stimulating ideas to the page than many a more ponderous psychiatric tome. Psycho-analysts will find the second half difficult going and psychiatrists will *a fortiori* find it hard to read. But they should try.

EDWARD GLOVER.

TEXTBOOK OF MEDICINE

Principles of Internal Medicine. Editors, T. R. Harrison, Paul B. Beeson, William H. Resnik, George W. Thorn, and M. M. Wintrobe. (Pp. 1,590; 245 illustrations. £4 10s.) London: H. K. Lewis. 1950.

This massive work is a textbook on a new model and the editors are to be congratulated on the care and thought so evidently devoted to its design and execution. The book begins with a brief but excellent chapter on the approach to the patient. A section follows in which the cardinal manifestations of disease are discussed, and then one on such

physiological topics as fluid and electrolyte balance, intermediary metabolism, and electrophysiology. These sections represent an attempt, which is wholly praiseworthy and largely successful, to integrate the "pertinent content of the preclinical sciences with clinical medicine." The authors' names are sufficient guarantee of the excellence of individual articles: Harrison on "Circulatory Failure," Wintrobe on "Anaemia," and Pickering, this country's sole representative, on "Headache" need only be cited to show the standard which has been set.

Part III is on reactions of the body to stress and antigenic substances. There are general reviews of the reactions to injury, of the psychological reactions to stress, and of the principles of immunity. These are succeeded by more conventional accounts of the clinical pictures which result from these reactions. The rest of the book conforms to the traditional pattern of the textbook of medicine, the diseases of known causation being classified aetiologically and the remainder anatomically. This part of the work maintains the high standard of the earlier section; the descriptions of disease are concise and illuminating; the principles of treatment are set out with precision and economy of detail; and each article concludes with a short bibliography, all of which show careful selection and a commendable lack of national prejudice.

The viewpoint of these writers is entirely to-day's. Probably the book's arrangement would have appeared fantastic to a teacher of medicine in 1900; for the same reason, it is not unlikely that the view of medicine instinct in its design will be outmoded in 1975. Nevertheless it is highly to be commended; there is no book on the market which represents more faithfully the outlook of the physician with a training in experimental physiology, and it is this outlook which dominates academic medicine in the English-speaking world to-day. In spite of its formidable bulk it can be recommended to the student who is in transition from his preclinical to his clinical studies; it will provide a sorely needed bridge between the two.

R. BODLEY SCOTT.

THE GORILLA

The Anatomy of the Gorilla. The Studies of Henry Cushier Raven and Contributions by W. B. Atkinson, H. Elftman, J. E. Hill, A. H. Schultz, W. L. Straus, Jun., and S. L. Washburn. Arranged and Edited by William King Gregory. A collaborative work of the American Museum of Natural History and Columbia University. The Henry Cushier Raven Memorial Volume. (Pp. 260; 116 plates. \$15. or £4 17s. 6d.) New York: Columbia University Press. London: Geoffrey Cumberlege. 1950.

The sumptuous manner in which this volume is published must surely be the envy of all those workers in the field of mammalian anatomy who chance to live in lands where lavish grants for the publication of scientific monographs are not available. The volume is published as a memorial to Henry Cushier Raven, a man remarkable for his attainments as a collector and preserver of museum specimens and for the possession of a very charming and modest personality. Unfortunately he did not live to complete his projected monograph on the anatomy of the gorilla, and the preparation of the work for publication was undertaken by the late Dr. John Eric Hill. It is doubtless owing to the untimely death of both the original author and the reviser that the final publication is so regrettably uneven in its contents.

This unevenness is made evident by the fact that there are no figures or description of the central nervous system, nor, save in Schultz's account of the growth of the head, is there even any mention of the brain. The bones, though figured so far as the muscular attachments are concerned, are not described, and the loss of this is felt all the more since in some cases an explanation is surely needed—as, for example, in the figure of the clavicle (Plate 38), where an area for a "costo-clavicular articulation" is marked towards the lateral third of the bone. In this particular

instance the absence of any explanatory text is all the more to be regretted, since the very unsatisfying figures of the mounted skeleton throw no light on the matter, and nowhere in the volume is there any reference whatever to articulations. A work that totally neglects descriptive accounts of the osteology, syndesmology, and the whole central nervous system hardly deserves the title under which this volume is published. The illustrations are reproduced in a style that can only be described as magnificent; but again there is the same unevenness of quality. Although many of the drawings of muscles leave little to be desired, some, especially certain of those depicting the viscera (such as Plate 88B), are hardly worthy of reproduction in any manner.

The volume is a triumph of modern book-making; but, if we are honest, we must confess that on closing it there comes a realization that a monograph on the anatomy of the gorilla remains to be written.

F. WOOD JONES.

A DOCTOR'S STORIES

Just a Medley of Amusing Tales and Interesting Medical and Legal Experiences, recorded by An Old Retired Scotch Doctor. (Pp. 80. 5s.) Reigate: George J. Heatt and Son.

I have read this book with much pleasure. The author tells of his student life in Aberdeen and Vienna, with many interesting stories of his experiences. Later in his 25 years of general practice he held the post of divisional surgeon to one of the divisions of the Metropolitan Police, and there encountered a host of interesting personalities of all sorts.

Many of his stories cover the war period and travel cruises. They are related in a pleasant and readable form and should prove a useful storehouse for storytellers in all walks of life. A fund of humour is especially valuable to medical practitioners in difficult times like the present, and a perusal of this booklet will prove both interesting and instructive.

G. MACFEAT.

VENEREAL DISEASES

Veneral Diseases described for Nurses. By R. C. L. Batchelor, M.A., M.B., Ch.B., D.P.H., F.R.C.S.Ed., M.R.C.P.Ed., and Marjorie Murrell, M.B., B.S., D.P.H., F.R.C.S.Ed., M.R.C.S. (Pp. 218; 43 figures. 12s. 6d.) Edinburgh: E. and S. Livingstone. 1951.

This little book, written for both male and female nurses, contains in some 200 pages all that, or even more than, they need know about venereal diseases and patients suffering from them. It contains an adequate description of most of the venereal and allied diseases which bring patients to V.D. clinics, together with their symptomatology and treatment. The descriptions are clear and most of the illustrations first-class, though the figures on pp. 12 and 152 contain no references to the numbers given in the captions. There is an excellent section on ethical and sociological considerations.

A few criticisms both constructive and destructive may be allowed. The language is perhaps rather too technical and more suitable for a medical student than a nurse, who might be hard put to it to explain the meaning of ophthalmoplegia, for example. The impression is given that chancres are almost always "hard," that "salvarsan" commonly causes death, that a provocative injection of neoarsphenamine is of considerable value, and that a Herxheimer reaction in syphilis may be avoided by starting treatment with small doses of penicillin. A description of the procedure for lumbar puncture would be useful. Complementary for complementary (p. 55), and specula for speculae (p. 164), will presumably be included in the next edition, which will soon be needed, for this excellent book should have a wide circulation.

T. E. OSMOND.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 16 1952

KING GEORGE VI

The country and the Commonwealth mourn the passing of a beloved and kindly King who by his steadfast bearing, devotion to duty, and manly example made all his peoples truly members one of another, bound with hoops of steel in the adversity of war and knit together in a firm resolve to build a new world in the peace that yet hovers on the horizon. He gave us the strength that comes from the unity of a Monarch with his people. When Britain stood alone the King and his family stood there in the centre of our life, enduring in full measure the ordeal of the battle that raged over the cities and ports of a besieged country. If the constitutional sovereign of a free people has become in much of his significance a symbol, King George VI was a symbol not of the pomp and circumstance of palaces but of a devoted father of a family who in his unaffected simplicity came close to the heart of the common man, and in this became so much the more a King.

The British Medical Association mourns the passing of its beloved patron, and the thoughts of its members move in deep sympathy with the widowed Queen and with Queen Mary. The ties between the medical profession and the throne are in some ways closer than those of other sections of the community. Doctors assist at the birth of the Prince or Princess, destined to take up the heavy burden of sovereignty. They give their counsel in health and their skill and care in sickness. Chosen because of their character, knowledge, and wisdom, they assume an overwhelming responsibility when called to the sick-bed of a King or a Queen. King George VI was sorely tried by illness in his too brief life. The courage and persistence with which he triumphed over a distressing disability of communication he displayed in the grave illnesses of his last years. As a naval cadet at Osborne he had a severe attack of pneumonia. In the early weeks of the 1914-18 war he was operated on for appendicitis; but he saw active service in the Battle of Jutland. Then a period of serious ill-health ended in an operation for duodenal ulcer at the end of 1917. It was in November, 1948, that his

medical advisers issued a bulletin stating that "the King is suffering from an obstruction to the circulation through the arteries of the leg, which has only recently become acute; the defective blood supply to the right foot causes anxiety." In commenting on this the *British Medical Journal* said: "The medical profession will join with the rest of the community in heartfelt sympathy with the King in his present disablement—a sympathy heightened by their knowledge of the pathology of arterial disease." It was indeed highly probable that the local condition of the leg was symptomatic of a more widespread involvement of the arterial system, and his medical advisers must have been gravely concerned about the condition of the cerebral and coronary arteries, a concern which they naturally had to keep within their own counsel. Further bulletins were issued, and in March, 1949, the country learnt that lumbar sympathectomy had been performed with a view to improving the supply of blood to the right foot.

In a review at the time of the value of sympathectomy in the treatment of organic arterial disease it was stated in these columns: "The majority of arteriosclerotic subjects are old, their expectation of life is limited, and the risks of operation are greater. Even so, lumbar ganglionectomy may be of distinct value in some of these cases. The operation is best reserved for patients under 60. . . ." The King's recovery from the operation was uneventful, and happily he gained relief from his distress and the circulation in the right foot improved. But the state of the King's cardiovascular system must have continued to be a source of grave anxiety to his medical attendants. His sudden but peaceful death from coronary thrombosis ten days ago, on February 6, was the sad and now all-too-familiar outcome of the condition diagnosed in 1948 and bearing no relation—it seems unnecessary to add in a medical journal—to the disease of the lung for which resection was carried out in September of last year. About three months after signs of inflammation in the lung structural changes appeared of such a nature as to compel the King's doctors to advise resection, a serious operation from which the King made a magnificent recovery. The nature of the lesion in the lung has not been officially declared, but the following statement in the *Manchester Guardian* of February 7 reflects informed opinion on it: "Although a name was never officially given to the illness which necessitated the King's sudden operation on September 23, most doctors thought that the 'structural changes' first announced on September 18 were those of cancer of the lung."

His late Majesty, as an account on page 386 shows, followed his father's example in the interest he took

in the world of medicine. He was closely identified with the British Empire Cancer Campaign, and it was only a fortnight before his accession that he had presided in the House of Lords over the annual meeting of that body. In 1933 he opened the International Paediatrics Congress, saying, "Take care of the young, and the country will take care of itself." It was indeed with the young that he seemed to be at his happiest, and it was in 1921 that he arranged for the first of his boys' camps, made up of 200 public school boys and 200 boys from working-class homes. Two years before this he had become President of the Boys' Welfare Association, under whose aegis the camps were run. Here was a direct contribution to social welfare and to what was known later as "positive health." As Duke of York he lived in the camp, took part in the sports and the games, and joined with zest in the camp-fire singsongs. His interest in the health and welfare of the young was further shown by his presidency of the Barnardo's Homes, the Boys' Welfare Association, the National Playing Fields' Association, and the National Safety First Campaign. After the death of his father he was made chairman of the Advisory Council set up to help in administration of King George's Jubilee Trust, which by endowments and grants aided young people in their games and sports. Another sign of his attunement to the age in which he was living was his concern with industrial welfare, manifested when he accepted the presidency of the Industrial Welfare Society. It was sad that one who played such an active part in promoting health and welfare should have suffered so much from illness, and it was with personal knowledge of what he owed to medical research that at the opening in 1950 of the National Institute for Medical Research at Mill Hill he said:

"The work of the Institute exemplifies that spirit which inspires the State and science to work together for the health and happiness of mankind. . . . Many families here at home and, indeed, throughout the world have reason to be grateful for the benefits which have been brought about by medical research."

Medical men and women, knowing the nature of the King's recent illnesses and operations, must often have feared that his life might end after protracted suffering and anguish of mind and body. The great shock and grief at his sudden death must in the nature of things be tempered with the knowledge of what he may have been spared. During his life King George VI witnessed the flowering of a new epoch in medicine, with its especial triumphs over so many dire infections. His daughter, Queen Elizabeth the Second, will, we may hope and pray and expect, witness the conquest of the diseases that afflicted her father in the last years of his reign.

QUEEN ELIZABETH II

In the name of the British Medical Association and of the medical profession of this country we join with all loyal subjects in offering homage to the new sovereign. Like her late father, Queen Elizabeth II is the centre of a happy family life, and with her husband has earned the deep affection of the peoples over whom she reigns. She has already graced many a medical occasion, and is an Honorary Fellow of the Royal College of Obstetricians and Gynaecologists and of the Royal College of Surgeons of England. When, as Princess Elizabeth, she was admitted Honorary F.R.C.S. on December 5 last year she referred with feeling to the astonishing development of surgery since the College had received its first Royal Charter. As contrasted with the destructive uses man had made of scientific knowledge, "surgery at least," Her Royal Highness observed,¹ "was one field in which man's wisdom and energies had been devoted consistently to human good."

Like her great namesake, Queen Elizabeth comes to the throne at the young age of 25. Upon her youthful shoulders there now falls the heavy burden of public duties and State occasions and all the detailed work that is undertaken by a constitutional sovereign. Yet the Queen has, perhaps, a higher duty, and that is to her children, to her family. The young Queen is also the young mother, and it is devoutly to be hoped that those who give her "good advice and counsel"—to use the words of the other Queen Elizabeth on her accession in 1558—will see that the stresses and strains of Queenship are not borne at the expense of the fulfilment of motherhood.

THE PLACE FOR VOLUNTARY WORK

King Edward's Hospital Fund for London is an independent charity which has contributed many valuable ideas to the National Health Service. Perhaps the Emergency Bed Service is the best known of its creations, but it has been extremely active in setting up schools to train hospital administrators and caterers, in conducting research into many aspects of hospital organization and life, in investigating hospital costing on behalf of the Ministry of Health; in fact, in acting as the higher cerebral centres of the hospital service. Through its intelligence, independence, and great wealth it has been able to soften the

¹ *British Medical Journal*, 1951, 2, 1517.

rigidity of State bureaucracy and to guide the managers of the Health Service into useful creative action.

The Civil Service was originally a purely managerial body controlling enterprises already in being, and recent legislation has given it work it was never intended to be able to do. The 1946 Act made it responsible for creating a new national medical service, and the knowledge and wisdom of King Edward's Fund and the Nuffield Provincial Hospitals Trust was brought in to give practical help in its planning. Civil Servants were aided to make these plans realities by the many public-spirited people who gave their time to the new boards and management committees as they had formerly to the voluntary hospitals. It is often forgotten that the Health Service has grown from, and is still shaped by, voluntary work and the efforts of charity.

To many social reformers charity has a suspicious and unpleasant sound. The Welfare State, it was hoped, would replace the inadequate, haphazard, and what was sometimes looked on as the patronage of the poor by the rich by granting the right to all citizens equally to obtain aid from an impersonal State. And it would do away with sweated labour and working without pay and ensure full employment at a reasonable wage. This has been the belief of many ordinary people in the past four years. They have paid high weekly insurance contributions and high taxes and imagined they were paying for a full health service in complete running order. Charity was out-moded, volunteers no longer needed.

And now King Edward's Hospital Fund for London, jointly with the National Council of Social Service, has put us once again in its debt¹ by analysing the position of the unpaid worker in the hospital service. It is the first survey of its kind, and only an introduction to its subject. Many criticisms can be brought against it: that it contains too many personal opinions and not enough hard fact, that it wanders into irrelevant discussion of the administration of the Health Service, that it is not cogently written and will not make the public impression that the subject deserves. But it does bring forward two matters of the first importance. One is that since 1947 the need for voluntary service has increased, not vanished, and the supply of volunteers and money does not yet meet this need. And the other is an elucidation of the significance of voluntary work.

Man is a social animal. He has the instinct to live a communal life, which means not merely to exist in an aggregation of individuals but something more—to work with and aid his fellows. This fact tends to

drop out of sight in the gulf between discussions of individual rights and national demands. Men are more than units of personnel or production; they are not naturally occurring electronic brains in suitable mobile housing. They are born with the need to react emotionally on one another, and the giving of service is one outlet for this need. It is an outlet which may be channelled and directed but must not be stopped up, because to do so is to cut men off from one another and begin the disintegration of the community. This is a truism of mental health, and it is ironical that the daily life of peace should fail to offer the outlet of war. Where now is the spirit of Dunkirk? None of the problems such as housing and tuberculosis have been attacked with the vigour which went into military victory, and this is partly because people have not understood their own local responsibility in the peace effort and the opportunities for service.

Voluntary Service and the State indicates many useful parts the volunteer can play, both in and out of hospital. Ward orderlies, visitors, and interpreters, the trolley-shop which sells things to patients, the library service (how many patients realize that the books are mainly gifts and the librarians volunteers?), out-patient receptionists, canteen workers, clerical assistants to the blood transfusion services . . . the list of ordinary hospital jobs is enormous, and the work, particularly in chronic sick and mental hospitals, of great importance. But the opportunities outside also are great. In some areas district nurses, health visitors, the hospital car service, aftercare, and home helps are organized by voluntary societies. Sitters-up who will stay with a patient all night, home physiotherapists, aid to patients on discharge from hospital, provision of special food and appliances—the services vary from area to area according to local needs and initiative, and they want both trained and untrained people to give a few hours a week of their time.

But the first need is publicity. It would be good for patients to be told how much is being done for them by voluntary effort. They will not then take it for granted, and some of them will later wish to offer their services by way of thanks. There ought to be more articles in local newspapers on the kind of work being done and the need for more volunteers. Hospital committees can explore the possibilities of direct contact with local groups such as the employees of large firms to see whether friendly relations and help can be stimulated. The hospital could be a centre of local community life and not just a unit of the national medical service, and voluntary work at all levels has an important part to play.

E.S.R. IN ANAEMIA

When blood is diluted with its own plasma, the erythrocyte sedimentation rate (E.S.R.) is increased, a fact first demonstrated by Fåhræus¹ and repeatedly confirmed. This accelerating effect of dilution, and the frequent association of anaemia and an increased E.S.R., led laboratory workers to conclude that anaemia *per se* increased the E.S.R., quite apart from other pathological conditions, and they then sought means of correcting for the anaemia. Of the numerous methods of correction evolved, those of Wintrobe and Landsberg² and of Hynes and Whitby,³ both only applicable to the Wintrobe E.S.R., became generally accepted.

These corrections have not been popular with clinicians, who tend to prefer the Westergren E.S.R., with its normal range smaller and its abnormal range much greater than the Wintrobe values. Furthermore, the Westergren E.S.R. appears to correlate better with the clinical assessment of patients (Sinton,⁴ Gilmour and Sykes,⁵ Shackle⁶). However, the correction theory has limited the value of the Westergren E.S.R. in anaemic patients, since there is no accepted method of correcting it for anaemia, and it has thus become customary with anaemic patients either not to estimate the E.S.R. on the grounds that it will necessarily be raised, or to disregard an abnormal result.

Doubts about the validity of the various methods of correction have been repeatedly expressed. Recently Terry⁷ gave reasons for regarding them not only as fallacious but also as unnecessary. He considered that it was irrational to apply the same method to the many different varieties of anaemia, and that, since the correction charts were based on dilutions of normal blood, their significance for specimens of anaemic blood was obscure. He argued that there was no proof that anaemia increased the E.S.R. and submitted clinical and experimental evidence showing that simple hypochromic anaemia is frequently associated with a normal E.S.R. He concluded that anaemia *per se* does not increase the E.S.R., and suggested that the small abnormal cells of hypochromic anaemia resist rouleaux formation or that its plasma is deficient in rouleaux-stimulating properties.

Drs. J. C. F. Poole and G. A. C. Summers in a series of convincing experiments reported elsewhere in this issue have now demonstrated that in iron-deficiency anaemia this increased stability of red cells in suspension is a property not of the plasma but of the cells, possibly the result of anisocytosis. They also found that in symptomatic anaemia the plasma exerted a strong accelerating influence, that in post-haemorrhagic anaemia both cells and plasma behave more like normal blood, and that in macrocytic anaemia the cells behave less predictably.

It seems clear from these findings that an abnormal E.S.R. in the presence of iron-deficiency anaemia is

significant, and indicates either that the anaemia is not due to uncomplicated blood loss (of which menstruation, childbirth, and haemorrhoids are the commonest causes) or that some complicating illness such as phthisis is present; in either case further investigation of the patient is necessary. In symptomatic anaemia the problem seems academic, since the condition of which the anaemia is symptomatic is also likely to be the cause of the abnormal E.S.R. Thus the lengthy and little-disputed reign of the correctionists is now being challenged, and clinical interpretation is at last replacing laboratory deduction.

THE HAIR

True hair is peculiar to mammals, and its primary purpose seems to be the prevention of heat-loss in warm-blooded animals. In man hair is almost vestigial, but it remains of some importance and much interest. The form, abundance, colour, and length of hair are used as anthropological criteria. In social affairs much time and labour and money are expended upon its adornment, and the chemistry and physics of hair-dyeing, setting, and waving alone have added important chapters to scientific progress and to biomolecular studies. The effects of radiation on hair started the development of modern radiation therapy and are used experimentally in assessing the surface changes caused by radiation from new sources. Similar effects constitute an important indication of the degree of injury sustained in atomic warfare.

Hair has played an important part in the elucidation of the problem of pigment formation. Tyrosinase, which is essential in the process of pigmentation, contains copper. Rabbits fed on a diet from which copper was excluded showed a greying of the previously black hairs, together with a general loss of hair.¹ Genetic, endocrine, and ageing factors are responsible for baldness and are interdependent. It is said that baldness is less common and is seen later in the Chinese than in the Caucasian.

Much of the more recent knowledge on this subject was brought together in a symposium on the growth, replacement, and structure of hair organized by the Section of Biology of the New York Academy of Sciences.² Study of the hair coats of animals, especially sheep, has given a better understanding of observations upon the growth of hair in man and of related genetic problems. Histological studies emphasize the outward motion of cells in the epidermis and appendages from the innermost cells of the Malpighian layer. The tonofibrils within the epidermal cells, regarded as the precursors of keratin, lie perpendicular to the skin surface in the epidermis, but they are parallel to the long axis of the hair. A soft keratinization is characteristic of the epidermis and is indicated by a granular and a glassy layer. Chemically such keratin has a low sulphur content and is unstable, as evidenced by continuous desquamation. Hard keratin found in the appendages has a

high sulphur content, has strength, and is chemically inert, a fact explained by the oxidation of cysteine to cystine, providing cross linkages between the polypeptide chains making up the tonofibrils and welding them into a closely knit mass.

Proliferative activity in the hair follicles in animals occurs periodically, passes in a wave from the ventral to the dorsal surface of the body, and is followed by a period of rest. It is interesting that in some animals the period of lactation, when the cutaneous circulation has to supply extensive mammary tissues, is associated with a cessation of hair growth.

The physician has always made use of the reflections in the skin of the health and tone of his patient and of the presence or absence of general disease. These features are often amplified in the appendages and particularly in the hair. Here may be seen indications of the race and sex and age of a subject and perhaps something of his strength and temperament. Major disturbances, as of nutrition or endocrine function, of emotional stress or infective disease, are readily detected. Increasing knowledge of the nature of hair growth and structure is likely further to help the general physician in his assessment of a patient and the dermatologist in his understanding of skin diseases.

MERCURY FOR CHILDREN?

Are mercurial preparations destined to drop out of the pharmacopoeia in the near future? There is evidence in the paediatric literature of most continents that mercury is no longer being prescribed with the old-time characteristic assurance. The need for taking stock became apparent when Warkany and Hubbard^{1,2} published their finding of appreciable amounts of mercury in the urine of 30 out of a total of 41 children with pink disease. In 1947 Fanconi and his co-workers³ recorded observations on 56 hypersensitive children who showed untoward reactions to mercury. Of the 56 cases 39 were regarded as examples of "calomel disease." In this week's issue of the *British Medical Journal* Dr. M. L. Thomson and two other members of his team have collected the clinico-pathological facts relating to five children who were all between the ages of 11 months and 3½ years when they were in hospital, each of whom was known to be taking mercury by mouth at regular intervals for periods extending over months, and all of whom presented a clinical picture of nephrosis.

It may be that we are on the fringe of a better understanding of the implications of mercury treatment. We know that inhaled mercury fumes, ingested mercury pills, and napkins soaked in biniodide solution may all give rise quite easily to symptoms of poisoning. Exceptionally, toxic side-effects can be traced over a period to the time when an amalgam dental fitting was first inserted. A further complicating feature is that an individual who shows signs of sensitivity to one mercurial compound cannot be relied upon to react to all such compounds. It is important that we should not be

driven from our pharmacopoeia through fear. The immediate need is not to jettison useful drugs but rather periodically to review therapy in use and be sure that the value justifies the risk. Teething-powders, worm powders, and grey powders have become too convenient a medicament. The object should be to do away with as many powders as possible and at all costs to discourage any tendency on the part of the parents or the family to regard daily medication as essential to health in childhood. The greatest risk to which a child may be exposed is subjugation to a routine of this kind, with no pauses to review the situation.

FUNNEL CHEST

Although the deformity of funnel chest, or pectus recurvatum, was described in the sixteenth century, it is only in the last few years that treatment has been undertaken, or indeed been considered possible. The lesion consists of a funnel-shaped depression of the lower sternum, at the apex of which is the xiphoid process. It is usually symmetrical, but not always so. The costal cartilages are drawn backwards with the sternum, and there is sometimes also a transverse groove across the lower chest wall. Although this groove resembles Harrison's sulcus of rickets, funnel chest has nothing to do with this disease, nor is it the result of respiratory obstruction. The deformity is due to a congenital abnormality of the diaphragm: this was first shown by Brown¹ and has recently been elaborated by Brodtkin.² If the anterior portion of the diaphragm, developed from the septum transversum, is deficient, the central tendon is short and pulls on the xiphisternum. If the lateral portions are also short the costal arch will be grooved.

A mild degree of funnel chest is common and symptomless, but more severe degrees lead to secondary effects. The patient is round-shouldered, with sloping ribs, and underweight. The lungs are compressed, and breathing is inefficient. Respiratory infections are common—perhaps because coughing is ineffectual. The most important symptom is dyspnoea on exertion; this is probably cardiac rather than pulmonary in origin and due to rotation and compression of the heart. A systolic murmur is sometimes heard. The pulse rate and blood pressure are unstable, and an electrocardiogram may show minor abnormalities such as axis deviation or inverted T waves. The visible deformity may result in emotional disturbance, and asymmetrical breast development at puberty increases the disfigurement in girls. Although a neurosis may be engendered, cardiac symptoms usually have an organic basis.

Methods of operative treatment, based on the aetiology described above, have been developed in America. In infants it is sufficient to detach the xiphoid from the sternum and free it from its diaphragmatic attachments. A more elaborate procedure is necessary in older children, when the sternum and costal cartilages

have become fixed. Lester³ prefers to operate before the age of 5, but good results are obtained in older patients, even adults, in whom symptoms are relieved, though the deformity cannot be entirely corrected. The sternal costal cartilages below the second are resected subperichondrally; the xiphoid is detached and the diaphragmatic attachments released. A transverse osteotomy of the sternum is done by a wedge resection of the outer table about the third segment. The sternum can then be elevated, obliterating the depression. It must be held in the new position either by wires attached to an external ladder splint, which maintains a stable chest wall until union has taken place, or else by inserting under it a free graft of cartilage or rib.² Several series of cases have been reported, with no deaths and very few complications. The majority of patients with this deformity have it in a mild degree and do not require treatment. Very few operations have been done in this country, but in the presence of a large depression surgery for the relief of physical or sometimes even mental symptoms should be considered.

GREAT ORMOND STREET

On February 14, 1852, St. Valentine's Day, the children's hospital which is now known all over the world as "Great Ormond Street" first opened its doors, and three days later the first patient was admitted. The foundation of "The London Hospital for Sick Children" and its later development are described in an article on another page. Readers of this will see that Dr. Charles West, the moving spirit behind the birth of the hospital, was determined from the start that it should be an educational centre not only for doctors and nurses but for the enlightenment of mothers. Within a few years of the hospital's opening a "model infant nursery" was set up, and this was an appropriate beginning to the work of prevention which has always been well in the foreground at Great Ormond Street, and which the Institute of Child Health continues to foster.

During the hundred years of its existence the hospital has had on its staff many of the giants of nineteenth- and twentieth-century medicine—among them Gee, Cheadle, Barlow, Still, Garrod, and Hutchison. The last-named, whose 80th birthday was celebrated four months ago, has written a little nostalgically of "the 'beautiful' examples of rickets and infantile scurvy, or the cases of acute rheumatism with enormous nodules,"¹ which are now no longer seen at Great Ormond Street, but it has been owing to the work of men of his stamp that, as he himself says, "disease has become less 'picturesque' with each generation"—a change for which to-day's patients can be devoutly thankful.

One other side of the work at Great Ormond Street has been of outstanding importance. Before Florence Nightingale set on foot the reform of the Army nursing service during the Crimean War, which began in 1853, the status of nurses was remarkably low, with the result that few, if any, women of education and feeling took

up nursing as a career. Miss Nightingale's work eventually brought about a revolution in public opinion, with consequent great changes in the method of recruitment of nurses. But it was a gradual revolution with many setbacks. While the struggle to improve nursing in the large general hospitals was going on there was being established at Great Ormond Street a tradition of children's nursing which has not only been of inestimable benefit to sick children everywhere but which was of the greatest help to Miss Nightingale's main cause—the importance and dignity of nursing. The hospital to-day carries on that tradition. Only a few weeks ago we published a paper from Professor A. Moncrieff and Sister A. H. Walton² describing an innovation in the nursing of sick children at Great Ormond Street which might well be adopted in children's wards throughout the country.

SCIENTIFIC EXHIBITION AT THE ANNUAL MEETING

A welcome innovation at the Joint Annual Meeting this year in Dublin will be a scientific exhibition staged by members of the British and Irish Medical Associations. Demonstration booths of the familiar exhibition pattern are to be set up in a large hall, and they will contain displays which, in the words of the relevant resolution of Council, "should consist of refresher demonstrations on particular subjects of current medical interest, presented at specified times . . . and illustrated by pathological specimens and other appropriate exhibits." The exhibitors will be expected to be on hand at certain times of day to talk about their demonstrations to their colleagues and to answer questions. The exhibition will be open only to members of the profession.

This excellent idea owes much to Mr. Lawrence Abel, who recently brought back from the U.S.A. particulars of the similar exhibition held at the annual meetings of the American Medical Association. Mr. Abel has also visited Dublin to arrange practical details with officers of the Irish Medical Association. The success of the exhibition now rests with the members of the two Associations, who are asked to come forward with exhibits. It is greatly to be hoped that there will be a good response to this invitation. A show of this sort, providing opportunities for informal discussion with workers in different fields of medicine, should certainly be a most attractive addition to the programme of the Annual Meeting. Time is short and floor-space limited. Prospective exhibitors are therefore urged to apply for space for their exhibits without delay. Full details are given at page 379.

The half-yearly indexes to Volume II of the *Journal* and the *Supplement* for 1951 are now being sent to members who receive them regularly and to subscribers. Members who have not previously asked for the indexes to be sent regularly to them can obtain copies, post free, on application to the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1; those wishing to receive the indexes regularly as published should mention this.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

FREQUENCY OF MICTURITION

BY

H. P. WINSBURY-WHITE, F.R.C.S.

Senior Surgeon, St. Peter's and St. Paul's Hospitals; Lecturer, Institutes of
Urology and Child Health, University of LondonBLADDER-NECK IRRITATION WITH LITTLE OR
NO OBSTRUCTION

The commonest type is the patient who has chronic frequency of micturition but in whom repeated examinations of the urine have failed to show any abnormality. This clinical entity is found at all ages and in both sexes. The frequency is usually more marked when the patient moves about than when sitting or lying; it is aggravated in bouts for no apparent cause; and it is associated with urgency. In children especially, the urgency sometimes results in diurnal incontinence and it may also be associated with enuresis; this last manifestation is sometimes carried on into adult life. Cerebral impulses, such as those due to the sound of running water or emotional disturbances, are more potent in initiating micturition in these patients than in normal individuals, and in some patients with enuresis profound sleep probably acts by lessening cortical control. There is as a rule no residual urine. In adults the bladder capacity rarely reaches above 4 to 6 oz. (114 to 170 ml.). The patients tend towards occasional attacks of cystitis.

In long-standing cases there are sexual disorders of various kinds, the commonest of which is impotence. Lumbar fibrositis (lumbago), sacro-iliac disease, sciatica, neuritis, and arthritic changes, especially in the digits and lumbar spine, may also occur; headaches and nausea, bouts of *Bact. coli* urinary infection, and some residual urine in the bladder are common. Because of the development of fibrosis at the bladder neck there are generally obstructive changes here.

In the early stages the frequency is commonly regarded as a form of nervous-system disorder, because the urine is sterile; later, when coliform bacilli begin to appear, the case is diagnosed as one of *Bact. coli* urinary infection; if one of the rheumatic manifestations dominates the clinical picture, the diagnosis is according to this.

Obviously the initial reason why this group of cases is not understood is that the examination of the urine throws no light on the case. It is only as a result of routine cystoscopy and more particularly of urethroscopy that it becomes clear that chronic inflammatory processes can exist in the posterior urethra without either evidence of their presence in the urine or a urethral discharge.

Pathology

The routine endoscopy of all cases of disturbances of micturition allows one to visualize the pathogenesis of these chronic cases, and since 1936 it has been my practice to carry out urethroscopy and cystoscopy in all children sent to me for investigation.

Boys.—Small granulomata or occasionally actual polypi are found in the prostatic sinuses or on the verumontanum; a smooth rounded projection (hillock) on the margin of the internal urinary meatus or on a lateral lobe of the prostate

is also not uncommon. The granulomata and polypi apparently arise at the orifices of normal or adventitious openings in the posterior urethra. Some hillocks are possibly associated with the lymphoid follicles found in the posterior urethra of children. In certain cases the verumontanum appears to be atrophied. The ceiling of the membranous urethra is at times conspicuously the seat of chronic inflammation, the gland orifices being dilated and the surrounding mucosa shaggy or covered with thickened epithelium. Congenital urethral stricture occurs most commonly in the mid-penile urethra. The narrowing is identified by noting the "gripping" in passing sounds; there is no localized area of scar tissue such as one sees in acquired strictures in adults, but a funnel-shaped narrowing. Sometimes there is a persistent small amount of residual urine in the bladder. The importance of chronic meatitis, seen from time to time in circumcised children, should not be overlooked. Sometimes there is an ulcer which may be very chronic and result in contraction of the meatus, inflammation of the urethra, and attacks of cystitis. After infancy a prepuce which is adherent to the glans invariably covers smegma; untreated, the condition persists indefinitely, and ultimately causes urethritis and cystitis.

Girls.—Urethral granulomata are not seen so often in girls as in boys, but they are quite common in women who have suffered from frequency of micturition or enuresis since childhood. In girls hillocks, generalized urethral narrowing, and residual urine in the bladder are seen from time to time. Some consider that it is not abnormal for children to be unable to empty the bladder completely, but the fact remains that such children are usually subject to disturbances of micturition. A simple chronic inflammation of the vulva is sometimes seen, which is generally associated with urethritis but not with vaginitis. Exceptionally, vaginocopy will show a granuloma of the cervix. Many cases of enuresis fit into one or other of the above categories.

Women.—Disturbances of micturition are so usual and so chronic in women that they have been regarded as an almost inevitable part of adult life. In addition, the female urethra has commonly been considered a small and inoffensive part of the urinary tract. For more than 20 years it has been my practice to make a urethroscopic examination in all my women patients with disturbances of micturition, and this routine has made it obvious that the cause of the symptoms often lies in the urethra. In some there is a continuation of the pathological changes which are seen in childhood; in others the lesions have been acquired later. Before the urethroscope is introduced a size 24 Charrière metal sound is gently passed, when it can be noted whether there is any gripping, tenderness, or bleeding. On urethroscopy the commonest pathological finding is an inflammatory process involving the posterior urethra and the front of the trigone (urethro-trigonitis). In the more chronic cases inflammatory polypi are seen projecting around the internal urinary meatus; these are sometimes found only in a rudimentary form (hillocks), or there may be a rigidity of the internal urinary meatus (fibrosis).

Men.—When disturbance of micturition has been present since childhood, granulomata and polypi are generally conspicuous, patches of leucoplakia may be found anywhere in the posterior urethra, and hillocks are to be noted projecting from the lateral lobes of the prostate or at the

internal meatus. The meatus itself is often raised well above the floor of the prostatic urethra. Sometimes a generalized urethral narrowing is obvious on attempting to pass instruments. In old-standing cases rectal examination may show thickening in the regions of the prostate and seminal vesicles, but in early cases very often no change can be felt.

Bacteriology and Effect on Upper Urinary Tract

So far no specific organism has been identified to explain any of the inflammatory processes mentioned. These infections in most cases seem to establish themselves insidiously. This is in contrast to the cases in which frequency develops acutely with a urethral discharge and perhaps with terminal haematuria when a venereal origin is highly probable, although a scanty and intermittent gleet is common enough in adults in whom there is no such association.

Intravenous urograms often disclose persistent areas of poor renal function, indicating localized sclerosis; and moderate degrees of pelvic or calyceal dilatation are common enough. These pathological changes manifest themselves clinically in attacks of pain or pyelitis.

Treatment in Children

In dealing with patients, whether children or adults, who show only the pathological changes described above, it will be found that, although antibiotics will sometimes cause the symptoms to lessen or to disappear for a short period, their recurrence is the rule.

Meatitis.—This requires a simple meatotomy. The cut should be made parallel with and just to one side of the fraenum, reaching almost to the coronal sulcus. No sutures are required, but the raw surfaces must be separated each day for five days by inserting the tip of a sound between them.

Granulomata or Polypi in the Posterior Urethra.—Dilatation of the whole urethra with metal sounds, on one or two occasions at intervals of not less than two months, is the best treatment. Very exceptionally fulguration of the polypi is required.

Small Amounts of Residual Urine.—When there is 2 oz. (57 ml.) or less, urethral dilatation as above should be carried out, except that this treatment may have to be continued longer.

Localized and Generalized Urethral Contraction.—The assessment of these cases will depend upon knowing what the urethral calibre, according to age, should be. In a child of 8 a size 16 Charrière sound should lie comfortably in the urethra without gripping. Ages and sizes then are as follows: add one size for each extra year; take away one size for each year less than 8. This gives the whole scale for children. Treatment should be by dilatation.

Adherent Prepuce.—The prepuce must be freed by gauze dissection, and the parts subsequently kept separate by the daily application of a liquid paraffin dressing and retraction of the foreskin over a period of at least five days.

Simple Vulvitis.—The daily application of penicillin or a sulphonamide ointment should be carried out for two weeks, and repeated after a week's rest if necessary.

Acute Cystitis.—Copious fluids, alkalis, and antibiotics are used during the acute stages. Later any local cause must be sought.

Treatment in Women

It is a very interesting fact that small hillocks and flimsy polypi will disappear from a woman's urethra as a result of a single instrumentation. This change is accompanied by an improvement in symptoms. Bulky hillocks and fleshy polypi, however, must be treated by coagulation through an operating urethroscope in the in-patient department.

Out-patient treatment is adequate in many of the cases. This consists of the original cystoscopy and urethroscopy,

and then urethral dilatation with straight metal sounds at steadily increasing intervals between the treatments. The intervals are conveniently arranged as follows in weeks: 3, 4, 6, 8, 13, 26, 39, 52. Wyndham Powell urethral dilators should be used. Three phases follow a urethral dilatation: reaction, improvement, and relapse. Any one of these phases may be short or prolonged. Unfavourable symptoms will be encouraged by unskilful treatment, due commonly to too frequent or excessive dilatation. It often takes the urethra two weeks to settle down after a properly conducted instrumentation, and that is why three weeks are allowed to elapse in the first instance.

Treatment in Men

The same method of treatment should be carried out with men, except that curved metal sounds are used. In treating men, however, it is a matter of experience that if all are investigated as out-patients a certain proportion will suffer complications of the instrumentation. This is because damage is sometimes done to an already diseased prostate. My rule therefore is to admit to hospital all men over 50 who require instrumental investigation. Post-prostatectomy and bladder-growth cases accustomed to regular inspection are exceptions to this rule. All the other investigations, however, are carried out in the out-patient department. Even with in-patients the same danger threatens, but this may largely be avoided by carrying out any necessary endoscopic examinations immediately before operation. For instance, when prostatectomy is indicated the gland is enucleated within 20 minutes or so of the cystoscopy. Those cases of bladder-neck irritation which are found not to require operation—that is, when the residual urine is not more than 4 oz. (114 ml.) and the gland is not adenomatous—are referred back to the out-patient department. They can usually be successfully treated by intermittent urethral dilatation.

BLADDER-NECK IRRITATION WITH OBSTRUCTION

Children

The finding of large amounts of residual urine in very young children is not uncommon in children's hospitals. In deciding treatment the first need is to determine whether or not the dilatation is due to a mechanical obstruction. This question should be approached by studying the bladder neck in cystograms. As the opaque medium in the bladder will take longer than usual to throw a shadow because the bladder is dilated by the residual urine, the exposures should not as a rule be started until an hour has passed; they can then be repeated at about hourly intervals until suitable pictures are obtained. It can then be seen whether the posterior urethra as well as the bladder is dilated; should this be the case, it may be assumed that posterior urethral valves are present. These are usually impossible to see through a urethroscope.

The absence of posterior urethral dilatation leaves the choice between neuromuscular derangement of the bladder wall and stenosis of the internal urinary meatus—and it is often difficult to decide which is responsible. Opening the bladder and excising the internal meatus usually results in a reduction in the amount of residual urine, but if a large quantity was originally present it can be expected that a considerable amount will still remain after operation. Transplantation of the ureters into the bowel, sometimes after a preliminary period of bladder drainage, may be the best course to follow.

Women

In women mechanical obstruction of the bladder neck definitely occurs occasionally, generally because of fibrosis; sometimes there are quite large amounts of residual urine, even to the extent of causing visible bulging of the lower abdomen. No treatment less than a bladder-neck resection

will suffice for these cases. I prefer to do a suprapubic extirpation with the diathermy needle, keeping a finger in the vagina while the removal is being accomplished. This is a safeguard against perforating the anterior vaginal wall. Small amounts of residual urine—under 4 oz. (114 ml.)—will in due course be cured by intermittent urethral dilatation.

Men

There are several main types of prostatic change: adenomatous, fibrous, fibro-adenomatous, and malignant. Any of these may be associated with prostatic calculi or vesical diverticulum, which are found most commonly with the fibrous prostate and least commonly with a malignant prostate.

Adenomatous prostates are characterized by a frequency of micturition which is nocturnal rather than diurnal and, on rectal examination, by the "elastic" enlargement of the gland. Unlike these cases, the fibrous prostate declares itself well before the age of 50. The frequency of micturition is equally marked by day and night; on rectal palpation the prostate is small and firm or cannot be detected at all; and cystoscopy does not reveal the typical projecting mass of adenomatous tissue. The two types of tissue in a fibro-adenomatous prostate can be recognized either on rectal or on cystoscopic examination. Hardness, irregularity, and fixity are the characters of well-developed malignant disease of the prostate, but quite a proportion of these cases are discovered only on microscopy of enucleated or resected tissue. Irregular projecting masses on the front of the trigone, seen at cystoscopy, may give rise to the first suspicion. Prostatic calculi are usually discovered only on x-ray examination.

Treatment of Prostatic Obstruction

It is always best to enucleate an adenomatous gland. Whichever route is employed the following principles should be observed: on the basis of blood, urine, clinical and x-ray tests decide whether a one- or two-stage operation is to be done; avoid pre-operative urethral instrumentation, except as an immediate preliminary to operation; after the gland is out, excise a wedge of tissue from the posterior margin of the prostatic cavity, keeping a finger in the rectum while this is done; stop all bleeding and remove tags under direct vision. With this routine thrombotic complications are rare, and most cases are properly done in one stage. If attention has been paid to all these points a very narrow suprapubic drainage tube can be used and thus convalescence hastened. If, however, the bladder is subsequently drained entirely by urethral catheter then a well-trained team who thoroughly understand catheter management is essential for the convalescence. The ease with which clot due to secondary haemorrhage can be removed and the adequate control of a renal infection stress the advantage of suprapubic over urethral drainage. When all goes well, urethral catheter drainage undoubtedly shortens convalescence, but there are many cases in which the course is not straightforward and the convalescence is therefore prolonged. Sometimes this means that the urethral catheter has to be left in unduly, and this adds to the danger of subsequent urethral stricture. In all cases it is necessary to know what instrumental precautions to take as an extra safeguard against post-prostatectomy obstruction.

Transurethral resection operations for adenomatous prostates set special problems to the surgeon, particularly in the control of primary haemorrhage. Many surgeons, therefore, wisely reserve this form of treatment for fibrous prostates in cases in which residual urine is not excessive—personally, not above 8 oz. (227 ml.). When there are larger amounts there is a good deal of uncertainty about how often resection will have to be done. With the latter type of case I prefer to do a wide suprapubic resection of the fibrosed tissue with a diathermy needle.

A malignant prostate does very well without any operation at all, if the patient can empty the bladder. Many of these cases keep wonderfully well for years, simply on

stilboestrol. If there is residual urine a transurethral resection may be necessary. Bad cases—that is, those with much residual urine—may require a suprapubic resection.

OTHER CAUSES OF FREQUENCY OF MICTURITION

Certain other important though less common causes of increased frequency of micturition require mention. All are easily identifiable.

Primary Upper Urinary Tract Disease.—As a cause of frequency upper urinary tract disease will be detected by evidence of it in the urine or on x-ray examination. It must not be forgotten, however, that renal changes are often secondary to lower urinary tract disorders.

Genito-urinary Tuberculosis.—Frequency with this condition will be accompanied either by characteristic bladder lesions visible on cystoscopy or by palpable changes in the genitals which are equally characteristic. Discovery of the tubercle bacillus in the urine is the final proof.

Diabetes.—Thirst, frequency, and polyuria in a child, and the discovery of sugar in the urine, are the essential features. In adults thirst may not be remarked upon.

Vesical Calculus.—In this part of the world to-day vesical calculus is nearly always secondary to a bladder-neck obstruction which dominates the clinical picture. In the stone areas of the Orient, however, where vesical calculus occurs commonly in young children as a deficiency disease, as it did in the last century in this country, there is in addition to the increased frequency the characteristically persistent terminal haematuria.

Foreign Body.—This is generally seen in a young patient, from whom the history of the insertion of an object is, not always forthcoming. Radiography and cystoscopy may be necessary.

Urethral Stricture.—In addition to the frequency, difficulty in micturition and perhaps an intermittent urethral discharge are likely features. Obstruction in the anterior urethra to instrumentation is diagnostic.

New Growth of the Bladder.—When frequency is associated with a new growth haematuria is an outstanding feature; in such a case the growth is usually malignant. Cystoscopy at once directs the further procedures along the right lines.

Retention of Urine with Overflow.—This is mentioned mainly to stress the importance of placing the hand on the lower abdomen in the course of a urinary investigation.

Pelvic Tumours.—Pressure of tumours from outside the bladder tends to cause symptoms which are more marked in the erect posture. Bimanual pelvic examination generally makes the diagnosis clear.

Vesico-vaginal Displacement.—The downward drag of the bladder in the erect posture causes an aggravation of the symptoms which may be associated with some degree of incontinence of urine. Restoration of urethral support should accompany the colporrhaphy.

Cystalgia.—An irritable bladder without a local cause is something which is seen less and less as the surgeon's skill in searching improves; but a solitary vesical inflammatory lesion (Hunner's ulcer) is exceptionally present.

Conclusion

By far the commonest causes of frequency of micturition are bladder-neck changes and a localized irritation in the posterior urethra. The latter is commonly a mild simple chronic inflammatory state, but later may be followed by other changes.

Children as well as adults are affected.

Urethroscopy is essential in many cases.

The great majority of patients respond to local treatment.

‘MEPILIN’

For menopausal disorders,
pre-menstrual tension and dysmenorrhœa

THE ASSOCIATION of methyl-testosterone with ethinyl œstradiol as in Mepilin permits a marked reduction to be made in the effective dosage of œstrogen for the control of menopausal symptoms.

Advantages of Mepilin are :—

1. Production of an increased sense of well-being
2. Avoidance of undesirable side effects such as breast turgidity and pelvic congestion
3. Reduced risk of inducing uterine hæmorrhage or withdrawal bleeding

Mepilin contains ethinyl œstradiol 0.01 mg., and methyl-testosterone 3 mg.
Bottles of 25 and 100 tablets. Dosage—Menopause: 2 to 6 tablets daily.
Pre-menstrual tension and dysmenorrhœa: 2 tablets daily from 10th to 22nd day of menstrual cycle.

THE INTERNATIONAL ASSOCIATION OF GERONTOLOGY AND RAPID PROGRESS OF GERONTOLOGY*

BY

V. KORENCHEVSKY, M.D.

(From the Oxford Gerontological Research Unit, Oxford)

Although this paper considers rapid progress of gerontology and the International Gerontological Association, the scheme presented can be applied to any international biological or medical association and congress.

Basis of the Report

The final solution of all basic gerontological problems depends entirely on biological and medical research in this field; and this applies to other aspects of gerontology, such as the socio-economic, and their practical applications in life. In this paper, however, only methods for the rapid progress of gerontological medical and biological research work are considered. This by no means ignores the great importance of the socio-economic aspects of gerontology. It is simply that the medical and biological research must receive a certain amount of unavoidable priority; otherwise gerontology, and in particular geriatrics, will preserve artificially the sickly and miserable plants of senility in their artificial greenhouses. If gerontological research should lag behind the socio-economic welfare measures, the proportion of useless old people among the nations will steadily increase, and at a tremendous cost useless years will be added to their lives and not useful life to their years.

Scientific and medical research workers must leave the care of old people and all other aspects of socio-economic problems to the governments, municipalities, and welfare societies. Science and medicine must concentrate all their efforts towards a rapid advance in gerontological experimental and clinical research. Of course, research workers will gladly give advice and assistance, if asked for it, to the agencies that are engaged in socio-economic gerontology.

Organization of the Man-power for Gerontological Research

As in every venture, man-power is as important as the venture itself. This problem, in its main aspects, was solved at the First International Gerontological Congress in Liège when we established the International Association of Gerontology.

In this Association are united all the gerontological and geriatric societies already established in most civilized countries. In those countries in which such societies do not exist, we are sure they will be formed in the near future and will join the Association. Even at present a powerful and well-organized scientific army is available for attacking the basic research problems of gerontology.

This was the aim of the First International Congress, and for its successful achievement we must be grateful to Professor L. Brull, who was the President of the First Congress and the first President of the Association.

Aims of the Next International Gerontological Congresses

It is logical to consider that there are two urgent aims of the future congresses—to equip the already formed scientific

army for a battle with the research problems of ageing and to move this army into action. Without proper equipment an army cannot fight. It is obvious that only the ways and means of achieving these aims could be discussed and approved at the Congress. The actual realization of these aims and the leadership in this great scientific battle have to be entrusted to the charge of the International Association of Gerontology.

It is most desirable that the Association, although responsible to gerontological societies, should not only organize the International Congresses but also report its own activities for their consideration and criticism. The more brains engaged in an active work the better for the venture. For this reason the Association will draw new inspirations and ideas from the congresses, and find not only encouragement but, let us hope, the necessary active support. Moreover, there is a danger that the Association, and especially its governing body, may become senile; but at the congresses they may find new and vigorous blood, absorb it, and thus become rejuvenated.

Organization of the International Gerontological Congresses

At present the international biological and medical congresses take the form either of large symposia organized on a world-wide scale, or, more rarely, of so-called institutes. Both consist of numerous reports, which later are published and can be read. Moreover, for critical consideration of their value it is much more convenient to read them than to listen to them; especially is this so since many reports are made in a language foreign to the speakers. Also, while many of those attending the congresses can easily read foreign languages, they experience great difficulty in understanding them when spoken.

In spite of all this, the usual congresses do some definite and important work: they spread a special knowledge among practitioners not engaged in research work and the public at large; and they provide an opportunity of establishing personal contact both between research workers and practitioners, and between research workers themselves.

Such congresses, however, contribute comparatively little to the rapid progress of research work, and therefore do not fully justify the heavy expenses entailed, the extensive organizing work done, and other considerable difficulties involved—for example, travelling by the delegates.

It is desirable, therefore, to adjust the congresses to the needs of the research worker, at the same time retaining their other useful points. To this end no revolutionary methods are advocated, but only a desirable adjustment and improvement in organization.

Research Sessions of the Congress

It is desirable, and probably necessary, to adapt the sessions of international congresses for the service of two main types of members. The usual "symposia sessions" should be preserved as being of most use to and interest for the practitioners in the fields of medicine and biology. Special "research sessions," however, should be introduced for research workers, to run simultaneously with the former. These research sessions are actually "brains trusts." They will consist chiefly of free round-table discussions by the specialists, for each specialty separately and also for the joint meetings of various specialties.

The aims of these sessions will be the organization and promotion of gerontological research work—in particular, those problems of gerontology which were investigated insufficiently or not at all; consideration will also be given to schemes and methods which might be used for investigation of these problems. In this way the most promising research schemes will be evaluated and recommended. In the following years the progress achieved in research will be discussed and the necessary adjustments and alterations made. The efficient work of these "brains trust" sessions is due not only to the collection of the individual opinions of

*The paper was read at the Opening Session of the Second International Gerontological Congress, held on September 9, 1951, in St. Louis.

the specialists; much more is it due to the specialists' combined efforts to obtain the best possible solution of the problems.

In fact, the "research sessions" have to be similar in organization to those international war committees which so successfully achieved the splitting of the atom. In a more general way this was suggested in my previous papers (Korenchevsky, 1946, 1947, 1948, 1950a, 1950b); and for the same idea of co-operation the whole organization of gerontological societies was devised and started in 1939 as an *International Club for Research on Ageing*. In 1950, for several good reasons, the club was superseded by the International Gerontological Association.

We are most grateful to Professor E. V. Cowdry, who, first in the history of international scientific congresses, had vision of the future and the necessary authority to introduce these sessions, so far in an abbreviated form, into the Second International Gerontological Congress.

Desirability of Permanency in the Work of "Research Session Committee"

There is little if any hope of completing the difficult task of the session in a few hours at the congress. Therefore it is desirable that the session should not only work through the whole duration of the congress but also become a permanent organization and continue its work in the intervals between the congresses. It can be given any name which the congress or the Association finds suitable. To avoid confusion it will perhaps be appropriate to call it simply "research session or committee of the International Association of Gerontology," and to use this name even during the congresses. It is desirable that in the intervals between the congresses, if the finances allow, the meetings of the session should be held once a year, preferably in those cities in which the large research centres interested in gerontology are situated. An executive committee of the session should meet more often.

Other Ways and Means for Rapid Progress of Gerontological Research

These have already been discussed in previous papers (Korenchevsky, 1946, 1947, 1948, 1950a, 1950b). They have been approved by the British Society for Research on Ageing. The proposed measures are similar to, or identical with, those discussed in the *Journal of Gerontology* (1948). The necessary measures may be summarized as follows:

1. Large funds must be available for financing gerontological research in all its manifold aspects.
2. In each civilized country permanent experimental and clinical laboratories or institutes for research on ageing have to be established, if they do not already exist, and be provided with adequate resources.
3. The formation of a sufficient number of groups of research workers, who would specialize in gerontological or geriatric research, is necessary. Obviously points 1 and 2 are essential for this purpose.
4. It is essential that the existing biological and medical laboratories and research hospitals should co-operate in gerontological research. Long-term grants must be provided for them.

Referring to my previous papers for the details concerning these measures, I should like to add a few words about the urgency of collecting the funds for gerontological research. Sooner or later the various governments must contribute to this research if they intend to prevent the prolongation of a useless life span and the premature ageing of their peoples.

Since it is difficult to arrange otherwise, voluntary contributions have to be collected by specially established foundations, national and international. One strong point in favour of an immediate start in establishing such foundations is that for every man there is a chance, sometimes a good one, of escaping cancer, arteriosclerosis, poliomyelitis, or some other dread disease; but at present nobody can avoid *premature*

and abnormal old age and premature death. Therefore our appeal is likely to be understood and supported especially by elderly persons who know what present-day old age means.

Executive Function of the International Association of Gerontology

It is obvious that the Association, strong in its organized unity and co-operative brain-power, representing in its special capacity many countries and nations and therefore possessing the greatest possible authority, is the only agency which can achieve the tasks outlined above. Since the governing body is an actual executor of the Association, especial care has to be taken in making this body truly representative of the respective gerontological societies. The closest co-operation between the governing body and research sessions is also desirable.

It must be recognized that the tasks both of the governing body and of the research sessions will be very difficult; indeed, this activity of the research sessions is the first attempt of its kind in the history of international co-operation in biology and medicine. The reasons why such a very difficult scheme is suggested are: (1) on the basis of experiments performed by other investigators and myself it is now possible to state that there are definite and practicable possibilities of research into the prevention of premature and abnormal old age and premature death; and (2) I personally have little doubt that, unless "research sessions" are introduced, the International Gerontological Congresses are bound to fail in their attempts to organize a rapid advance in research into old age.

Summary

A scheme to promote the rapid progress of gerontological research is suggested; the main items of this are:

1. The establishment of a permanent research session or committee which would work during and between the International Gerontological Congresses. The organization of this session or committee should be somewhat similar to that of the international committee for splitting the atom.
2. Provision of large funds both for gerontological research and for organizing work, in particular by means of the establishment of special foundations, national and international.
3. Formation of a sufficient number of groups of research workers in gerontology.
4. Co-operation of different existing biological and medical laboratories and research hospitals in gerontological research.
5. The International Association of Gerontology, in particular its governing body, is suggested as the executive agency of the scheme.

It has been known for some time that, although eserine and prostigmin both inhibit cholinesterase, only eserine applied to a nerve axon stops its activity. Likewise, stilbamidine, which has a curare-like action, also produces block, whereas D-tubocurarine does not. It has now been shown (*Nature*, February 2, p. 190) that this is a permeability effect. If the substances in very low concentration are injected into the insides of nerve axons they all cause block. The previous inactivity of some substances is the result of their inability to penetrate unaided into the axon and reach its impulse-producing machinery.

CENTENARY OF "GREAT ORMOND STREET"

BY

T. TWISTINGTON HIGGINS, O.B.E., M.B., F.R.C.S.

Senior Surgeon, Hospital for Sick Children, Great Ormond Street

In the England of a hundred years ago most children received but scanty consideration. Many of them died in infancy and so escaped much suffering. All too often those who survived were caught up in the industrial revolution. They toiled for long hours in coal-mine or factory, and lived in a deplorable environment of overcrowding and dirt. They were inadequately or wrongly fed. Even among the well-to-do there was little understanding of infant and child nurture, either physical or psychological. The death rate among children was appalling, and no wonder. Of London's 50,000 annual deaths, 21,000 were those of children under the age of 10. Rickets became known as "the English disease."

The grievously stunted, deformed, and battered bodies of many fellow citizens are still to some of us a vivid but grim memory of our youth, and our pathological museums display evidence of diseases of a type and degree now happily mainly a matter of historical interest.

Awakening of the Social Conscience

Yet, despite the general preoccupation of the public with industrial expansion and its indifference to the sufferings of children, the fire of reform was well alight among some social workers, ministers of religion, doctors, writers, and politicians, of whom Lord Ashley (later Lord Shaftesbury) especially championed the children's cause. In such a company, Dr. Charles West must always stand pre-eminent for his service to children. After two years as a medical student at St. Bartholomew's, West completed his course at Bonn, Paris, and Berlin, becoming M.D. Berlin in 1837. Then, after studying midwifery in Dublin, he practised as a physician and accoucheur, lecturing on midwifery at the Middlesex Hospital. But soon his main interest became focused on the diseases of infancy and childhood, a subject upon which he delivered a course of lectures. These were published in 1848 in a book which passed through many editions and was translated into several foreign languages. The material in it was based on West's experience as physician to the Royal Universal Dispensary for Children from 1839.

Institutional provision for sick children was at that time virtually confined to such out-patient dispensaries. The earliest in London was founded in 1796 in Red Lion Square by Dr. George Armstrong, and dealt with 1,200 patients annually. The Royal Universal Dispensary dated from 1816 in St. Andrew's Hill, Doctors' Commons. In 1822 it removed to the Waterloo Road to a special building designed to accommodate 50 to 100 beds. Owing to the death of the chief founder, however, the beds never materialized.

Few children were admitted to adult hospitals in those days. In 1843, of 2,363 patients in all the London hospitals only 26 were children under 10. Guy's had 15 "cribs" in a wooden building "over stables," which were demolished in 1850 and not replaced. Admission of young children to adult hospitals was generally prohibited, except for those requiring "amputation" or "cutting for the stone."

Dr. West Finds a Children's Hospital

West, moved by the urgent need of in-patient facilities for sick children, determined to found a special hospital for them. He had to contend with much opposition. The difficulties of nursing and the risks of infection were cogent arguments against such a project. The early experience of the Foundling Hospital was relevant; of the first 15,000 children admitted only 4,400 lived to grow up.

Yet in Europe there were already 17 children's hospitals, and West knew well of their growing success and value. He was undeterred by opposition and found strong support among senior colleagues, notably Bence-Jones, of Guy's, who gave much help in soliciting influential interest. West visited children's hospitals abroad and elaborated the practical details of his scheme, which was eventually launched at a public meeting on March 18, 1851. Soon it received powerful support. Queen Victoria subscribed £100 and became the first Patron. Lord Shaftesbury became president. Charles Dickens wrote a moving magazine article, and funds began to accrue. With a sum of £2,483 6s. 3d.

FIG. 1.—Dr. Mead's house at 49, Great Ormond Street after being taken over as the "Hospital for Sick Children."

in hand, the provisional committee was emboldened to seek a convenient house in which to make a start; and West happened upon 49, Great Ormond Street, a spacious late seventeenth-century house which had once been the residence of Dr. Mead, physician to Queen Anne, whose professional and social attainments had been matched by his lavish hospitality. The house (Fig. 1) had a large garden and afforded additional accommodation in Dr. Mead's former library and museum.

A lease was arranged and the necessary alterations were made to adapt the reception-rooms as wards and the library as an out-patient department. The institution was first called "The London Hospital for Sick Children," but subsequently the word London was omitted.

In December, 1851, the first matron, Mrs. Willey, was chosen from many applicants, and on January 2, 1852, Dr. Charles West and Dr. William Jenner were appointed physicians, and Mr. G. D. Pollock surgeon, the last-named being succeeded in March, 1852, by Mr. Athol Johnson. On St. Valentine's Day, 1852, the hospital was opened, and three days later the first patient was admitted. Eliza Armstrong, aged 3½ years, suffering from "consumption."

The Founder's Intentions

The accepted aims of the new hospital were:

1. To provide for the reception, maintenance, and medical treatment of the children of the poor during sickness and to furnish advice to the mothers of those who were not admitted.
2. To promote the advancement of medical science with reference to the diseases of childhood and to provide efficient instruction of students in the same.
3. To disseminate among all classes, but chiefly among the poor, a better acquaintance with the management of infants and children during illness by employing the hospital as a school for the education and training of women in children's nursing.

Administrative planning was thorough in detail. Only children from 2 to 12 years of age suffering from diseases peculiar to, or modified in some important respect by, their "early age" were to be admitted, and those "suffering from accidents or external injuries" were excluded. Infants under 2 were considered inadmissible, though exceptions soon came to be made with increasing frequency. Directions for washing, clothing, and diet, particularly the milk supply, were laid down, and facilities for education of the children in the wards and physiotherapy in the garden were arranged from the outset. A special fever ward was provided and close attention given to the control of infection.

The highest available standard of nursing was ensured by careful selection and strict discipline. Striking a patient, accepting a gratuity, or failing to "make children happy" meant instant dismissal. It is remarkable that in those "Sairey Gamp" days the frequent changes of staff recorded were due to incompetence rather than serious misdemeanours. Close attention was devoted to the recording of cases, the giving of formal lectures, and the instruction of students. The practice of the hospital was to be "open to all medical men on presenting themselves." To Dr. Jenner was allotted the formation of a museum and library. No one can doubt that the foundations of "Great Ormond Street" were well and truly laid. Proof was soon manifest in the rapid growth of the popularity of the young hospital. By October, 1853, the out-patient sessions, beginning at 8.30 a.m., were making the visiting doctors late for lunch, and more and more beds were needed. The original 10 became 20, and ultimately 30. Dr. Mead's old house was stretched to its utmost capacity. In 1858, after a successful appeal for funds at a festival dinner at which Charles Dickens presided, the adjacent house, No. 48, was acquired, providing much-needed relief. On the ground floor a "model infant nursery" was inaugurated which proved "an unqualified success."

Years of Expansion

From 1858 to 1872 the work of the hospital expanded steadily. Dr. Jenner retired in 1866, and his place was taken by Dr. Thomas Hillier. Four assistant physicians were added—Drs. George Buchanan, W. H. Dickinson, Sydney Ringer, and Samuel Gee. Mr. Timothy Holmes became surgeon and Mr. Thomas Smith assistant surgeon. The reforms and teaching of Florence Nightingale had already made possible the appointment of a trained lady superintendent and the birth of the hospital's modern nursing tradition.

In the late 'sixties plans were begun for building the special hospital which had always been West's aim. The old houses were becoming increasingly inadequate and troublesome. The foundation-stone of the new building designed by Mr. E. M. Barry, fronting Powis Place, was laid by the Princess of Wales on July 10, 1872, and the structure was completed in 1877 with accommodation for 120 beds, including the North Block for fever cases, the gift of the Misses Cohen, and the chapel, built and very generously endowed anonymously.

Meanwhile, in order to provide for convalescent children and to relieve in some measure the parent institution, the

lease of historic Cromwell House, Highgate, was taken in 1869. This was replaced in 1927 by the present country hospital at Tadworth Court, Surrey. Dr. West finally retired in 1875, having seen his children's hospital well established. To no one man does "Great Ormond Street" owe so much.

In 1880 the original houses, having become insanitary, were demolished. The need for further building became more pressing year by year, and in 1887, to commemorate Queen Victoria's jubilee, the children of the Empire subscribed a large sum and the South Wing, fronting Great Ormond Street, was completed. It was opened on June 4, 1893, the bed complement then being 240. The hospital now had a worthy building (Fig. 2) to which the only significant later addition was the Out-patient Department, the munificent gift of Mr. William Waldorf Astor, opened on August 4, 1908.

The old structure, so well known to many, endured until the birth of the modern hospital in 1937, but so rapid was the progress in paediatrics, in which Great Ormond Street's own pioneer influence never declined, that long before this

FIG. 2.—The second building, which was started in 1872 and added to in 1887 and 1908.

date the building of 1893 had become outmoded. Happily the significance of a hospital is not to be measured in bricks and mortar.

Research and Teaching

The reputation of the Bloomsbury hospital, based on the splendid work of the early staff in research and teaching and by that of their successors, notably Cheadle, Barlow, Lees, Owen, Morgan, and Pitts, was now firmly established and widespread. It was yet to increase and attain international stature. To the hospital's service were attracted men and women of the highest skill and vision as physicians, surgeons, nurses, and administrators.

Intensive study, unceasing investigation and research inspired the daily routine, promoting a steady advance in the knowledge and understanding of the ailments of childhood. The hospital's growing fame drew patients, often with rare diseases, from far and wide, so providing the unique opportunities which still prevail. Doctors from all over the world, and notably from the Empire, came in ever-increasing numbers, so that postgraduate teaching came to be a major activity.

New departments soon sprang up, notably those of bacteriology and radiology, with which the names of Nabarro and Ironside Bruce must always be honourably associated. The names of Garrod, Voelcker, Still, Batten, Colman, Poynton, Thursfield, Robert Hutchison, Langmead as physicians, and those of Arbuthnot Lane, Kellock, Corner, Waugh, Addison, Fairbank, and Tyrrell Gray as surgeons proclaim the quality of those vintage years which preceded 1914.

Available through the Medical Profession only

BEREX

Reg. Trade Mark

SUCCINATE-SALICYLATE THERAPY

Licensed under DOLCIN Patent. Patented in Great Britain 642971

IN TABLET FORM

For the relief of symptoms and
aid in the control of the systemic metabolic
disturbances found to be associated
with Arthritis and all Rheumatic
disorders

INDICATIONS

1. Rheumatic Fever.
2. Articular Rheumatism
(including Rheumatoid and
Osteo-Arthritis).
3. Non-Articular Rheumatism
(including Fibrositis, Neuritis
and Sciatica).
4. Arthritis associated with the
menopause.
5. Gout.

FUNCTION

A stimulating effect
on cellular respiration and
respiratory enzyme systems,
together with an increase of
oxygen utilisation by the
tissues (impairment in tissue
oxygenation having been
demonstrated in Arthritis).

Since **BEREX** is NON-TOXIC it may be prescribed
whenever massive salicylate therapy is indicated.

BEREX combines the following advantages: Prompt
relief of symptoms; correction of impaired tissue oxida-
tion; obviation of salicylate toxicity; suitability for
protracted administration.

Professional sample and literature on request to:

BEREX PHARMACEUTICAL CO., MEDICAL DEPARTMENT, 109 JERMYN STREET,
LONDON, S.W.1

SALICYLATE THERAPY

activity UP

toxicity DOWN

Experimental and clinical work shows Salicylamide to be a more effective analgesic and less toxic than other salicylates. The pure substance is available as tablets each containing 0.5G. Packings of 100 and 500 tablets.

In the Service...

Dietotherapy The physiological basis of "the longings of pregnancy" is, of course, plain hunger induced by the additional demands of foetal growth and the extra requirements for maintenance of maternal well-being.

For Mother and Child What expectant mothers "long for" is extra food in quickly accessible and palatable form. While treatment therefore suggests itself, present-day shortages and rationing make the purchase of supplementary foods a difficult problem, especially during pregnancy, when shopping activities are necessarily restricted.

In the Service of Obstetrics For satisfying the keen-edged appetite of pregnancy, the prescription is—a quickly prepared, tasty meal consisting of "proximate principles" and vitamins—as comprised in 'Ovaltine'. This delicious food supplement provides malt, milk, cocoa, soya, eggs and additional vitamins; it is readily available and is easily made up; meticulous laboratory control during different stages of manufacture ensures its entire purity and highest possible standard of quality.

For pre-natal alimention both for maternal strength and foetal development, 'Ovaltine' is the preferred food beverage.

Vitamin Standardization per oz.—Vitamin B₁, 0.3 mg.; Vitamin D, 350 i.u.; Niacin, 2 mg.

OVALTINE

Manufactory, Farms and 'Ovaltine' Research Laboratories: King's Langley, Herts

M356

The end of the first world war presented a new challenge, for it was clear that the old hospital buildings had outlived their day. In wards of 30 beds with inadequate sanitary arrangements, respiratory and gastro-intestinal infections could not be adequately controlled, particularly in infants. More rigid isolation was essential. Moreover, the comfort and health of the nursing staff, the growing demands of modern specialized treatment, research, and teaching could no longer be worthily met. Complete rebuilding became essential. A plan to rebuild the main hospital in the country, retaining only an out-patient department and a small emergency unit in Great Ormond Street, was abandoned, but as a compromise Tadworth Court was acquired with a view to its development as a country branch for suitable subacute and long-term cases. Pavilions were ultimately built in the park, and this branch has proved a valuable asset and offers great potentialities.

The Modern Hospital

Meanwhile, the planning of the new parent hospital was entrusted to Mr. Stanley Hall, and much thought was given to the details by the medical staff. To rebuild completely on the existing site without seriously disrupting the hospital's work presented no small problem. A golden opportunity seemed to offer itself when the adjacent Foundling Hospital site became vacant, but efforts in this direction failed, and it was decided to proceed in stages to minimize dislocation. In 1937 a start was made on the Nurses' House, facing Guilford Street, the foundation-stone being laid by the Princess Royal, the hospital's president. This building, when completed, gained for Mr. Stanley Hall the medal of the R.I.B.A.

The main hospital block was opened in October, 1938, by King George VI and his consort. It has since been dedicated as the Southwood Building in memory of Lord Southwood's outstanding chairmanship. The ward units each accommodate 10 children, four being in separate cubicles permitting complete segregation, and all giving on to open-air balconies. Each unit is equipped with bath-room, lavatories, sluice-room, kitchen, day-room, and parents' waiting-room. Experience has amply confirmed the value of these arrangements. Modern operating suites, routine pathological and research laboratory accommodation, museum, clinical lecture theatre, kitchens, milk-room, and so on are all on the most modern and generous lines. Beds are provided for nursing mothers.

The building of the next block, the new out-patient department, was interrupted by the outbreak of war in 1939. During the intervening years the out-patient work and that of other departments—radiology, records, and physiotherapy—have had to be carried on in buildings which were intended only for temporary use. This has been a grave misfortune, particularly when the demands of postgraduate teaching, expanding special departments, as well as the out-patient work itself have been surpassingly urgent. At long last it is hoped that the rebuilding programme may shortly be resumed. During the war children were evacuated to units in the country staffed by the hospital, leaving only a few beds for children in London, where air-raid casualties were catered for. On September 9, 1940, the hospital building was seriously damaged by bombing. Fortunately no one was injured.

Institute of Child Health

Towards the end of the war a gradual resumption of normal work became possible, and increasing attention was given to plans for the future. Additional special departments, the intensification of research, and the inauguration of the Institute of Child Health were proceeded with. In collaboration with the University of London, the trustees of the Nuffield Foundation, and the local authorities, the Chair of Child Health was founded, and in 1945 Dr. Alan Moncrieff, physician to the hospital, became its first occupant. Under the National Health Service the hospital was designated a "teaching hospital."

Such is the outline of a century of progress from the courageous venture of Charles West and his colleagues in

Dr. Mead's old house to the far-famed hospital of to-day. If in this brief history the doctors' part may seem to take precedence, they all would acclaim the essential contribution made by others: by their nursing colleagues, justly appreciated the world over for their skill, loyalty, and gentle devotion; by the splendid comradeship, wise counsel, and unstinted labour which has always come from the great-hearted lay folk who have served as members of the board of management or as professional administrators and faithful servants; by the general public, who have never failed in abundant generosity.

The fullest realization of the ideal of "Great Ormond Street" would see such a triumph of prevention as would soon empty the hard-pressed beds. That consummation is not yet, and the second hundred years open with no diminution of opportunity or weakening of purpose.

The two illustrations, kindly supplied by Odhams Press, Ltd., are taken from the book by Mr. T. Twistington Higgins entitled *Great Ormond Street* shortly to be published.

SCIENTIFIC EXHIBITION AT JOINT ANNUAL MEETING

The Council of the British Medical Association, in agreement with the Irish Medical Association, has decided to hold a scientific exhibition at the Joint Annual Meeting in Dublin this year (July 3-11). This is the first time that such an exhibition has been held. The exhibition will be in addition to the usual trade exhibition, and will be located in a large hall adjoining the latter. The object is to display new ideas in all branches of medicine to those attending the Annual Meeting.

On this first occasion the exhibition will necessarily be on a small scale. The pattern followed will be the exhibition held at annual meetings of the American Medical Association. Originality in the design of exhibits will be welcomed. Charts, drawings and transparencies, specimens, and other material can be enhanced by a judicious use of light and colour. The expenditure of much money is quite unnecessary. Many teaching hospitals and medical schools, for instance, already have exhibits of their work, and these could be taken to the Annual Meeting as personal luggage. No difficulty with the Customs is anticipated in this connexion.

Details for Exhibitors

A series of booths will be provided for exhibitors. Each booth has three walls, 8 ft. in height. The back wall is 10 ft. wide and the two side walls 6 ft. No part of any exhibit may extend above the top of the booth. A shelf, 2½ ft. from the floor and about 1 ft. wide, will be fixed all round the booth. Chairs will be provided. Fluorescent lamps will be fitted to the top of the walls, but lamps can be omitted on the request of the exhibitor if he wishes to show transparencies or cases with indirect lighting. Electric points (A.C. 200/240 volts) will also be fitted.

The exhibitor will be expected to pay the cost of the preparation, transportation, and installation of his exhibit, but no other expense will fall on him unless he requires alterations to the booth or special construction. Although it is hoped that the latter may not be required, any special demands will be dealt with sympathetically so far as possible. The cost of such alterations will be borne by the exhibitor.

No motion pictures will be shown in the booths, but separate arrangements will be made for these elsewhere. Exhibitors are expected to provide their own transparency cases for slides or x-ray films. There is ample free storage space for packing-cases.

Exhibits should be shown in the name of an individual person (or persons), who must be a member attending the Annual Meeting. The name of the hospital or institution at which he works may appear as part of the address.

The booths will be ready for the installation of exhibits by Sunday, July 6. Installation should be completed by 6 p.m. on Monday, July 7.

Reservation of Space

All applications for space at the exhibition should be received by March 31.

Those from the Irish Republic: To the Committee of Scientific Exhibits, Irish Medical Association, 10, Fitzwilliam Place, Dublin.

Those from the United Kingdom: To the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Intending exhibitors are urged to apply for space as early as possible. Applications must be accompanied by brief details of the proposed exhibit.

Demonstration of Exhibits

Admission to the scientific exhibition will be limited to members of the medical profession. The general public will not be admitted.

The exhibition will be open all day, but specified times will be allotted in the Meeting programme for viewing the scientific exhibits, when one or more competent demonstrators should be present in each booth to answer questions. Personal demonstration is of the greatest value to both visitor and demonstrator alike, and is without doubt the most important single item in ensuring the success of an exhibit.

Nova et Vetera**A SEVENTEENTH-CENTURY SCOTTISH CHEMIST**

William Davidson of Aberdeen. The first British Professor of Chemistry. Tercentenary Memorial Lecture given in Aberdeen, November 26, 1948. Aberdeen University Studies No. 129. By John Read, Ph.D.(Zurich), M.A., Sc.D. (Cantab.), F.R.S. (Pp. 32. No price.) Aberdeen: The University Press 1951.

Despite several illustrious names, Boyle and Hooke among them, chemists did not flourish on British soil in the seventeenth century. "The first British Professor of Chemistry" is the title that Professor Read gives to William Davidson (1593-1669?), of Aberdeen. Taking example, and perhaps advice, from his eminent fellow-townsmen, Duncan Liddel (1561-1613), Davidson decided that it was more desirable for him, "a third son, to . . . live industriously and honestly among foreigners than in poverty and degradation among [his] own countrymen." After graduating, therefore, he left for Paris, where he spent most of his active life teaching "chemistry" and practising medicine.

In 1644 a decree came into operation preventing foreign physicians not belonging to the Paris faculty from practising there. For some reason Henrietta Maria, the English queen, intervened on behalf of Davidson. He was thus appointed physician to the king, which absolved him from the interdict. In 1648 he became professor of chemistry at the Jardin du Roi, becoming thereby the first occupant of such a chair in France and also the first native of the British Isles to hold such a chair. In 1651, perhaps because of the rising intolerance of the Catholic party, Davidson left Paris for Warsaw to become physician to King John Casimir. In this new position he had to abandon chemistry, and his life became disturbed by wars and political intrigue. In 1669 he returned to Paris, but died soon after.

It cannot be said that Davidson's chemical achievements were important. He was a follower of Paracelsus (1493?-1541), whose doctrines, whatever their original value, had become by Davidson's time an obstacle to any scientific development. Professor Read discourses, with his usual charm and learning, upon the work of Davidson. In forming an estimate of its value he exhibits both patience and charity. These high virtues are peculiarly necessary in dealing with the later "alchemists," especially those of the Paracelsan school. The brochure is beautifully and suitably illustrated.

CHARLES SINGER.

Reports of Societies**BRITISH ALLERGISTS**

The annual general meeting of the British Association of Allergists was held at 1, Wimpole Street, on February 2. About 60 members and guests were present. At the morning session the chair was taken by Dr. D. A. Williams, president of the Society.

Allergic Rhinitis

Dr. H. A. LUCAS read a paper on the histopathology of rhinitis, which was illustrated by lantern slides of photomicrographs. He drew attention to the effect of various forms of non-specific injury leading to congestion of the erectile tissue and loss of the protective mucus layer which is normally in contact with the mucous membrane. Subsequently, paralysis of the ciliated epithelium with eventual metaplasia was associated with stagnation of mucous secretion. At this stage there was increased susceptibility to allergic sensitization. Infiltration of eosinophil cells and the presence of numerous plasma cells were demonstrated in allergic processes, whereas in acute infection there was a polymorphonuclear leucocytosis and in non-suppurative sinusitis a lymphocytosis.

The Eosinophil Response

Dr. J. PEPYS described an extensive series of experiments in animals and man designed to determine the primary and secondary factors responsible for local and general eosinophil responses. Evidence was put forward to show that the nucleotides, especially adenosine triphosphate, might be one of the primary factors in local responses, and guanylic acid in general responses. Secondary factors which enhanced the response were histamine or parasympathetic stimulation, either by drugs such as pilocarpine and acetylcholine or by direct vagal stimulation.

Limitations of A.C.T.H.

Professor G. W. PICKERING then gave an account of experiments carried out at the medical unit at St. Mary's Hospital. A survey of the literature had shown that the effects of adrenocorticotrophic hormone (A.C.T.H.) in asthma and hay fever were equivocal, except in infective asthma, in which they were conspicuously good. At St. Mary's the effect of A.C.T.H. on the skin's response to injury by serial dilutions of a number of substances had been studied. It had been shown that A.C.T.H. failed to modify the triple response caused by histamine, morphine, and pollen in sensitive subjects, but some modification of the effect of silver nitrate had been obtained. In two cases of atropine sensitivity the response to a patch test had been inhibited. The tuberculin test was definitely reduced in all cases. Others had shown that A.C.T.H. had no effect on the maximum breathing capacity of pollen-sensitive subjects exposed to the effect of pollen by aerosol inhalation. Professor Pickering had found no evidence that A.C.T.H. could affect either the liberation of histamine or its action on the tissues, although some forms of dermatitis and bacterial allergy were modified by the hormone.

Mode of Action of Antihistaminic Drugs

In the afternoon the chair was taken by Sir Henry Dale.

Dr. B. N. HALPERN (from Paris) discussed the mode of action of synthetic antihistaminic drugs, his observations being mainly based on animal experiments. In addition to their well-known antihistaminic and anti-allergic effects, these drugs had a powerful action in a number of other experimental and clinical syndromes, which possessed in common a disturbance of capillary permeability with the production of local or general oedema. The oedema fluid in these syndromes contained a high content of protein.

They included shock produced by injection of colloidal dyes, egg-white and dextran induced oedema of rats, acute pulmonary oedema, histamine shock, infective oedema, and various forms of inflammatory reactions. It could be assumed that histamine was the agent responsible for the production of all these conditions. The effect of antihistamines in preventing the haemoconcentration that occurred when animals were exposed to some of these agents was demonstrated. It was pointed out that adrenaline had a parallel effect, and Dr. Halpern suggested that both adrenaline and the antihistamines produced their effect by increasing the tone of the pre-capillary sphincters, thus lessening the flow of blood through the capillaries and favouring the reabsorption of oedema fluid. Histamine had a reverse effect. The synergistic effect of adrenaline and the antihistamines could also be demonstrated. This reduced the antagonism histamine-antihistamines to a particular case of their general competition on the smooth musculature. In reply to a question by Professor Pickering, Dr. Halpern said that the effect of antihistamines introduced locally into the skin differed from that of adrenaline, causing erythema and even local necrosis, instead of pallor.

Dr. Halpern suggested that the relatively poor effect of antihistamines in asthma might be related to the size of the antigenic particle. In asthma caused by sensitivity to large molecules such as those from feathers, hairs, horse dander, and animal proteins, their prophylactic effects were generally excellent. This contrasted with the results in asthma caused by dust, pollen, and bacterial infections where the antigen was supposed to be a polysaccharide molecule of rather small size.

Clinical Use of Antihistaminic Drugs

Dr. C. J. C. BRITTON then gave an account of the clinical use of antihistamines in allergic conditions. He had found them to be of greatest use in urticaria, angioneurotic oedema, and hay fever. In asthma in adults they were disappointing, but were sometimes valuable in cases of mild nocturnal asthma when any sedative side-reaction added to their effect. In asthma in children, however, they were very valuable when prescribed in the form of an elixir. The efficacy of the different drugs varied considerably with the individual patient, and it was essential to try a number of different types before abandoning their use. He drew attention to the many unpleasant side-effects of these drugs, and, though the more severe of these were uncommon, they could be extremely serious. Antihistamines were often individual in their action, and one drug might be tolerated when others would cause side-effects. He recorded his personal knowledge of patients who had been involved in car accidents following the use of antihistaminic drugs. Since in law the charge preferred against the driver who found himself in this predicament was "acting under the influence of alcohol or drugs," it was no defence to show that antihistamines were responsible. For this reason, patients should be advised to take the first dose of an antihistaminic drug at a time when it was convenient to observe any unpleasant side-effects that might develop, and never before carrying out any activity requiring an act of judgment. The first dose should always be small, and in the absence of side-effects it should be increased until the desired relief from symptoms was produced or side-effects noted.

Dr. Britton was not in favour of continuous administration of antihistaminic drugs prophylactically over a long period of time, but considered that they should be used chiefly as symptoms occurred. He was inclined to agree with certain American authors that the use of these drugs alone in hay fever favoured the development of pollen asthma. Certainly the proportion of cases of hay asthma now seen was very much greater than four or five years ago. Other factors might be important in this increase in hay asthma, but many things pointed to the antihistaminic drugs being the significant factor. A prolonged discussion followed these two papers.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Stellate-ganglion Block

SIR,—With reference to the work of Professor René Leriche (February 2, p. 231) on stellate ganglion infiltration in cases of cerebral ischaemia, it is interesting to note that similar results can sometimes be produced by ganglion-blocking drugs. May I refer to a recent article in the *Practitioner* (1951, 167, 641)? A more dramatic sequel occurred recently. I was called to see an old lady who had had her third attack of cerebral thrombosis in a convalescent home after being discharged from my wards at St. John's Hospital. When I examined her she was comatose and collapsed. Having no apparatus for a stellate ganglion block available, I ordered 5 ml. of tetraethylammonium bromide (T.E.A.B.) to be given by intramuscular injection at once. Two days later I returned to see the patient again. To my great surprise I found her dressed and downstairs, carrying a large pile of plates to help with the work of the housekeeper.

Another case occurred with a patient convalescing after hemiplegia due to cerebral thrombosis. She had been sent home from hospital on a trial holiday. She suffered another cerebral vascular accident and was sent back to hospital in an ambulance by her doctor, who doubted whether she would survive many hours. Again my intramuscular injection of 5 ml. of T.E.A.B. roused this lady from her coma, and the next day she had returned to the level of convalescence which had been previously present.

I feel that, while one swallow does not make a summer, these two rather dramatic examples of recovery may indicate that ganglion-blocking drugs have a place in the treatment of cerebral vascular accidents.—I am, etc.,

London, S.W.11.

TREVOR H. HOWELL.

SIR,—The very stimulating and interesting article by Professor René Leriche (February 2, p. 231) on stellate-ganglion block suggests to me that some of your readers may like to know of a simple technique which may be employed to effect the block. This was described by Virginia Apgar in *Current Researches in Anaesthesia and Analgesia*, 1948, 27, 53. She advises that the patient should lie in the supine position, with head turned away from the operator. A wheal is raised just above the clavicle, and immediately lateral to the sternal head of the sternomastoid muscle, and through it a 2½-in. (7.2-cm.) needle is inserted directly backwards until bone is met; this is the lateral part of the anterior aspect of the body of the seventh cervical vertebra. As the ganglion and sympathetic chain lie on the longus capitis and longus colli muscles, and not on the periosteum, the needle point is withdrawn for 0.5 cm., and after aspiration tests for blood and cerebrospinal fluid have been proved negative 5 ml. of 2% procaine solution is injected. Horner's syndrome develops very rapidly. The carotid sheath, containing the great vessels and the vagus, lies lateral to the point of injection. This technique is just as simple to perform as it sounds.—I am, etc.,

Westcliff-on-Sea.

Educating the Public about Cancer

SIR,—We were interested in Professor A. Rendle Short's letter on this subject (February 2, p. 276) and agree with the views he states. Since people are urged to consult a doctor directly the first symptoms of cancer appear it is logical that

they should be told what these are. There is no reason why careful educational work in cancer should not produce the same good results as in other diseases, notably tuberculosis. We have described elsewhere (*Lancet*, 1951, 2, 495) the experiences of the Chelsea Cancer Education Committee and the methods adopted in this borough. Briefly, our work so far has been the organization of lectures and discussions and the careful distribution of leaflets with a questionnaire attached to help us in learning more about the response to our efforts. The general opinion was expressed that fear of cancer is chiefly due to ignorance, and more patients would consult their doctors earlier if wise education were given. The replies have been almost unanimous in agreeing that the leaflet we issued is desirable and useful. It is our view that if this subject is presented with care it will do a great deal of good.—We are, etc.,

Stomach Tube in Trachea

SIR,—During the Christmas holiday I was reminded of the sensitiveness of the laryngeal reflex by a fit of coughing and choking caused by laughing and swallowing the contents of a liqueur chocolate at the same time. In the past I have several times seen expert laryngologists cocaine the cords before passing an endotracheal tube even under a general anaesthetic, showing the respect they had for the laryngeal reflex.

Thinking of these things, it was a great surprise for me to hear the anaesthetist say the other day while inducing a patient, "The tube is in the trachea," and to see her pull 6-8 in. (15-20 cm.) of Ryle's tube out of the larynx.

It is my custom before all stomach operations for the ward sister to pass a Ryle's tube into the stomach just before the premedication is given. The patient sits up, the tube is well lubricated, gently passed through the nose and paid out as the patient repeatedly swallows. In most cases no great difficulty is encountered. In this particular case the tube was passed by a nurse, who had a little difficulty, and the patient coughed quite a bit in the process. Nevertheless the tube was passed through the cords into the trachea and remained there until about two hours later when the anaesthetist wanted to pass her tube.

I do not know if this sort of thing is at all common, but I have never known it happen before. It makes one realize how important it is to make quite sure the tube really is in the oesophagus before giving an intranasal feed.—I am, etc.,

Rotherham.

ERIC COLDREY.

Vascular Spasm

SIR,—Your leader writer both on January 12 (p. 93) and February 2 (p. 262) this year deals with the problem of vascular spasm. On each occasion he advances the thesis that vascular spasm does not occur as the result of nervous intermediation. There are two suggestions supported, one of Kinmonth's that the collapse of the vessel is directly due to the fall in the general blood pressure, the other that the spasm is evidence of a proximal embolism or thrombosis and that according to this view it must always be associated with a preceding organic change.

Dealing with the latter view he seeks Pickering's support. Now Pickering in the *Lancet* a few months ago published a paper citing four cases of thrombosis in the limb vessels which had a previous history interpreted by him as that of embolism. This was purely an inference. If the symptoms and the antecedent history of at least one of them—the first—were examined there was an analogy with a case of Handler's (*Lancet*, 1949, 2, 514), in which previous to the planned embolectomy the similarity was complete. But on exploration no embolus or thrombus was found in the external iliac, which had been suspected. Instead there was a

marked spasm of a fair portion of the vessel's length. Pre-sacral sympathectomy was instantly performed and there was a dramatic release of the spasm. Handler has had brought to his notice similar instances in France. It would be preferable to accept this actual happening in support of a thesis than any amount of inferential data.

Vascular spasm in the retinal vessels undoubtedly occurs. Osman (personal communication) has seen its onset. Many authorities claim that they are far from uncommon. If the spasm is initiated by an organic change in retinal vessels it is a matter of surprise that pregnancy has not been associated with permanent deterioration of vision.

Because continuing spasm can be harmful, and because of the availability of therapeutic measures to relieve it and especially in view of the likelihood of its occurring, it appears to me to be a retrograde step to brand its suggested occurrence as a cliché.—I am, etc.,

Worthing.

JOHN SOPHAN.

Parkinsonism

SIR,—Dr. Hugh G. Garland's excellent article (January 19, p. 153) calls for comment. In his discussion of medical treatment I was surprised to read that he encounters toxic symptoms from "artane," sufficiently severe to prevent the use of the compound in doses above 20 mg. daily. It has been my experience that it is frequently necessary to use doses between 30 to 40 mg. daily to obtain maximum benefit, and I have a number of patients on such doses with only slight dryness of the mouth—a small price to pay for the benefit obtained—namely, relief of rigidity and increase in mobility.

Post-encephalitic cases are of course a separate group, and, as I have reported elsewhere, doses of artane as high as 100 mg. daily—or of "lysivane" 1,500 mg. daily—are, in my experience, frequently necessary to produce maximal benefit.

I must also disagree with Dr. Garland's statement that oculogyric crises never respond to any of the new remedies. I find both artane and lysivane materially reduce their frequency, but then, as such crises occur only in the post-encephalitic group, a higher dosage than he recommends is almost invariably required. It is probably true that amphetamine has a better effect in preventing these distressing crises, but again doses required are frequently of the order of 40 mg. daily or more. Again I find that, once patients have experienced the partial relief that may follow high dosage levels, they are only too glad to continue on the regime.—I am, etc.,

London, W.1.

OLIVER GARAI.

SIR,—I have read Dr. H. G. Garland's account of Parkinsonism (January 19, p. 153). In a mixed group of over 170 patients attending a clinic for the treatment of Parkinsonism I have used all the drugs he mentions in his article, and in certain cases I have made observations different from those of this author.

He states that there is a general feeling that the new drugs—i.e., those that he classifies as synthetic drugs of recent origin—are perhaps more effective than the old drugs and that they certainly seem to produce effects more quickly. My experience confirms this conclusion, but I do not think they represent the whole picture. I venture to suggest that, after treating a large number of cases with the new drugs recently introduced, the drug of choice is "lysivane." "Artane" is very useful when the action of lysivane is disappointing, and in only a few carefully selected cases is the use of "paranit" and "diparcol" justified. In a recent unselected group of over 50 cases treated with lysivane over the past two years I have had significant improvement in about 77% of all cases treated. I have entirely abandoned the use of the so-called old drugs, as I have found the new drugs so much more effective.

Dr. Garland adds that the main effect of artane is in the relief of rigidity and that its effect on tremor is very questionable. I have found that the effectiveness of both artane and lysivane is chiefly due to their action in diminishing tremor as well as giving almost complete relief of the rigidity.

FOR THE RELIEF of bronchial asthma, a choice of 'Neo-Epinine' preparations is available. Almost immediate relief is obtainable by oral inhalation of No. 1 Spray Solution, a plain 1 per cent aqueous preparation. The 20 mgm. compressed products, placed beneath the tongue, act within 5-10 minutes. Stubborn cases need oral inhalation of No. 2 Compound Spray Solution which contains 1 per cent of drug with 2 per cent of papaverine and 0.2 per cent of atropine methonitrate.

'Neo-Epinine'

Notes on High-Protein Diets

(1)

PROTEIN TREATMENT OF OBESITY

In the treatment of obesity by dietary correction the intake of calories should be limited to between 1,000 and 1,200 calories a day, and the patient should be supplied with optimum quantities of protein, vitamins and minerals. Thus the patient is forced to live for a time on his own fat resources and weight falls.

THE MOST PRACTICAL METHOD TODAY

At least 65 grams of protein should be given daily in order to ensure replacement of that lost by daily catabolic processes and to enable the patient to burn his own fat. In addition, protein has a high-specific dynamic action and a role in thyroid function.

Owing to the rather meagre dietary allowance available today, the most practical method of guaranteeing this daily amount of protein is to add Sanatogen protein supplement to the patient's diet. Sanatogen contains 95% casein combined with 5% sodium glycerophosphate and has a specific nutrient and tonic action. It supplies all the essential amino acids together, has a high rate of utilisation, and is easily digested and rapidly absorbed.

Sanatogen is the only proprietary protein supplement containing neither fats nor carbohydrate. The fact that animal protein is normally closely associated with fat enhances the value of fat-free Sanatogen in obesity diets.

EQUAL TO 6 OZ. LEAN BEEF DAILY

Taken three times daily, Sanatogen provides the patient with the equivalent protein nourishment of 6 oz. of lean beef. It is very easily administered. Normally taken mixed as a hot or cold drink, Sanatogen can also be sprinkled on food or mixed in cooked dishes. The routine addition of Sanatogen to the patient's diet in this manner is the most practical solution to the difficult problem of maintaining a high-protein intake today.

Practitioners who wish to carry out their own clinical tests will be given every help. Please write to the Medical Department, Genatosan Ltd., Loughborough, Leicestershire, for further information and medical samples.

SANATOGEN*for high-protein diet.*

Surgical Appliances bearing the name John Bell and Croyden have been supplied over a period of many years to the leading London Hospitals and Institutions, and have been increasingly prescribed by Surgeons and Physicians throughout the country.

Our extensive facilities for the supply and fitting of all types of Appliances are outlined below:

Private Consulting and Fitting Rooms.
Experienced Staff of Male and Female Fitters
always in attendance. Appliances made to
individual requirements by skilled technicians.
Fitters sent
or supplied from extensive stock. Fitters sent
by arrangement to any part of the country.
Hospitals supplied include Trusses, Surgical
Belts, Orthopaedic Appliances, Spinal Sup-
ports, Surgical Elastic Hosiery, etc.

Surgical Appliance Catalogue gladly sent

Telephone Welbeck 5555

It has been Dr. Garland's experience that, when a high dosage of these new drugs is given, patients will not tolerate taking so many pills and have voluntarily reduced the dosage so that the final amount taken is not much more than a placebo. I have found that my Parkinsonian patients are most conscientious when taking these tablets.

Finally, Dr. Garland states that oculogyric crises never respond to any of the above-mentioned drugs. These crises must be comparatively rare, as in 170 cases of all types I have met with oculogyric crises in only four instances, all of which responded favourably to lysivane.

Birmingham.

R. O. GILLHESPY.

A Modified Wrist Splint

SIR,—The illustration shows a method of moulding a simple slab-back plaster-of-Paris splint to give it greater strength and lightness. The patient sits with his forearm prone on a table level with his shoulder. The elbow is at right angles, and the fist clenched lightly. The slab is prepared in the usual way to reach from the knuckles to the elbow, and applied at once to the back of the wrist and forearm. A ridge is pinched up at the angle of the wrist and tapered distally and proximally. The plaster is allowed to set on the patient and then removed for drying before use. It can be sandpapered and varnished.

The advantages are (1) lightness; (2) reinforcement at the angulated part, in contrast with the weakness of a simple slab; (3) longitudinal ridging on the skin surface of the splint, which is less likely to cause soreness than the transverse ridging on a simple slab; (4) it is removable and washable; (5) it can be worn at work in most occupations; (6) it can be made quickly in the surgery by a general practitioner who has no access to perspex. It may be found advantageous to apply this technique to the making of perspex splints.

This splint has been found useful in the following conditions: (a) to relieve the pain of tenosynovitis; (b) sprains of the wrist joint; (c) paralysis due to cerebral thrombosis; (d) in the construction of a back splint for the knee of a patient suffering from painful osteoarthritis with flexion deformity; (e) in the construction of an instep splint for a patient with a dropped foot.—I am, etc.,

Hornchurch, Essex.

I. H. J. BOURNE.

Primary Generalized Arthritis

SIR,—A long-standing interest in chronic arthritis, stimulated by the mass of clinical material available to anyone who cares to pursue this subject, prompts me to comment on Mr. J. H. Kellgren and Dr. R. Moore's article concerning generalized osteoarthritis and Heberden's nodes (January 26, p. 181). For several years I have used the label "hybrid arthritis" to denote the class of cases they describe so accurately under the title of primary generalized osteoarthritis; hybrid, because the radiological changes of degenerative arthritis are associated with clinical changes in the hands apparently rheumatoid in nature. The difference

between the true rheumatoid hand and the apparent is very well illustrated in their Figs. 2 and 3. I am sure they are correct in describing primary generalized osteoarthritis as a clinical entity.

They make several individual points of importance. The acute onset, particularly in fingers and toes, may very well lead to drainage of a supposed infection, the more often now that the absence of pyrexia may be considered the result of using penicillin; the recognition of the significance of first carpo-metacarpal arthritis makes it fairly easy to recognize this class of case even when Heberden's nodes are absent; and these patients can be assured that they are not going to become what they most fear, a rheumatoid cripple, and this is of the greatest value.

It seems wrong to me to condemn surgical reconstruction of the larger joints *because* other joints are likely to be involved; better to relieve the burden where it is possible.—I am, etc.,

Liverpool.

E. N. WARDLE.

Extensive Resection of Small Intestine

SIR,—Mr. H. J. Croot's review on extensive resection of the small intestine (January 26, p. 195) prompts me to describe a case on which I operated a year ago.

This was a young man aged 32 weighing 10 st. 13 lb. (69.4 kg.) who, at laparotomy for an undiagnosed emergency, was found to have a strangulation of a knuckle of mid-ileum through a congenital hole in the apex of the mesentery. The anterior border of this congenital hole was the superior mesenteric artery, which had become occluded by pressure. The distal three-quarters of the small intestine was quite gangrenous, above which was 3 ft. (90 cm.) of congested oedematous jejunum with submucous and subserous haemorrhages, and above this was about 18 in. (45 cm.) of normal bowel up to the duodeno-jejunal flexure.

For the upper limit of the resection to have been through normal gut would have left him with only a few inches of jejunum, so I implanted the oedematous congested jejunum into the caecum, resecting about 18 ft. (5.5 m.) and leaving between four or five (1.2–1.5 m.) of proximal jejunum. I was certain that this anastomosis would not stand the slightest strain, so I did a caecostomy through the lateral wall of the caecum and passed a No. 22 catheter through the anastomosis upwards for about 10 in. (25 cm.).

He made a satisfactory recovery, and the caecostomy began to drain 36 hours after operation and the tube was removed on the fifth day. By the eighth post-operative day he was taking a normal diet, but his morale was rather lowered when he discovered a piece of tomato which he had swallowed a bare 10 minutes previously appear at his caecostomy. He was becoming grossly dehydrated, so a formal intraperitoneal closure of the caecostomy was performed on the 11th post-operative day. He was discharged from hospital on the 29th post-operative day weighing 8 st. 13 lb. (56.6 kg.).

A month later he was having his bowels open eight times a day. His appetite was insatiable. He weighed 9 st. 2 lb. (58.1 kg.). On a fixed diet of 90 g. protein a day the average nitrogen content of the urine was 8.2 g., whereas the faeces contained 13.67 g., showing that very little protein absorption was occurring.

Six months after operation he was back at work. He had completely regained his weight. His bowels acted only twice a day, with a normal formed stool. His appetite was normal. A barium meal shows that it takes one and a half hours for food to reach the caecum. He is absorbing protein normally.—I am, etc.,

Chatham.

B. E. CRAWFORD STANLEY.

Pink Disease and Antibiotics

SIR,—Pink disease (acrodynia), which was reported for the first time in this country as recently as 1922 by Thursfield and Paterson (*Brit. J. Child. Dis.*, 19, 27), now appears to be fairly widely recognized, and in view of the unsatisfactory methods of treatment, and risk of complications, I feel that the successful results I obtained in two recent cases following "chloromycetin" treatment are worth recording.

The first patient, aged 9 months, came to me as a temporary resident from Devon. He had been diagnosed as a case of pink

disease two months before my seeing him, and presented the typical signs of the disease: insomnia, anorexia, wasting, photophobia, profuse sweating, blue and swollen extremities, etc. The mother brought him on account of cough with vomiting, and I suspected pertussis. I prescribed chloromycetin, 50 mg. in capsules four-hourly, to be given in syrup, and this was kept up for the 14 days he remained in my care. During this time he commenced to take regular feeds. His photophobia disappeared. He slept well, gained weight, and in fact ceased to be the miserable child he was when first seen. I thought perhaps this was due in part to change of air and environment, and did not feel inclined to give the medical aspect the whole credit for the improvement.

Since then, however, I have had another almost exactly similar case. The child, a girl aged 1 year, was diagnosed in hospital as pink disease two months previously. She developed pertussis, and again I gave the same dosage as in the previous case, 50 mg. four-hourly. I can say quite definitely that the child was much better when examined a week or two later, and apart from slight insomnia all the earlier severe symptoms had disappeared. She is now quite well.

This case was particularly interesting because an older brother who was breast-fed developed acrodynia at five months. My present patient was bottle-fed and her symptoms occurred after an acute influenzal bronchitis at the seventh month.

Although the aetiology of this disease is still obscure the successful response to chloromycetin, which has been shown elsewhere to be effective against certain virus diseases, would appear to lend support to the hypothesis that pink disease is due to a virus infection against which adults are immune.—I am, etc.,

Uxbridge.

A. S. COOK.

The Nutritional Revolution

SIR,—Professor R. A. McCance in reviewing Sherman's book together with two other publications of the F.A.O. (January 19, p. 145) asks rightly whether the triumphs achieved in the improvement of nutrition were really so difficult to win. At the same time he reminds us of the hard task lying ahead in order to avoid the lurking shadow of world famine, especially if those who brought about this nutritional revolution fail to recognize that only an equally revolutionary increase in world food production may prevent what may be the greatest crisis in world history. The direct influence of the nutritional scientist in this respect may be limited by several factors. There are, however, some points which are not always sufficiently recognized in dealing with world food shortage, and in this respect his experience might be useful.

During recent years I referred repeatedly¹ to the work carried out by the Massachusetts Institute of Technology. Harris and his collaborators^{2,3,4} systematically analysed some years ago the diet of the poorest section of Mexican and Central American people, which mainly consisted of certain unknown plants growing wild on the Mexican plateau, further of a kind of specially prepared maize-bread (tortilla) and of cheap dried fish (charal). Meat and dairy products were no part of their diet. A surprising adequacy, even abundance, was found in their diet not only in calories but also in specific nutrients like calcium, iron, proteins, and vitamins. When a nutritional survey of 1,000 Mexican schoolchildren was carried out by the same scientists using identical laboratory methods, they were startled to find the nutritional status of the poorest Mexican children to be superior to that of 760 middle-class schoolchildren in Michigan. Other group surveys in Mexico also indicated a negligible incidence of detectable malnutrition or of deficiencies. This work came as a great surprise to all interested in nutrition, and it demonstrated that, in choosing a well-balanced diet, not only the calories and essential nutrients are imperative, but also that it should conform with the dietary customs of the race, and with the geographical availability of the food. Similar further studies would greatly enhance the conservation of available but not universally known food supplies and alleviate anxiety about the adequacy and possible increase of world food resources.

There are some other aspects of the world food problem which escaped the recognition they deserve. With the increasing control of acute infectious diseases and with the large-scale improvement of living standards and of public

health, the world population is increasing rapidly. This increase is characterized by the relative ageing of the whole population—i.e., while the total population doubled since the beginning of the century, the fraction of population over 60 years of age became roughly four times larger, with a tendency for further increase of the older age groups. While evidence is accumulating more and more that faulty nutrition may play an important part in many diseases beyond middle age, like hypertension, degenerative heart disease, and chronic mental disorders, comparatively little progress has been made in the elucidation of their relationship. All our effort would ultimately defeat its purpose should it not be possible to raise substantially the general health, working capacity, and mental vigour of those who survived to a higher age.

With the improvement of living conditions in Western civilized countries, like a 40-hour week, motor-cars, modern tools, and greatly mechanized production, the whole aspect of hard work has changed during the last generation. Even in the case of heavy manual workers the work output expressed in calories per day dropped by anything up to 30–40% in comparison with that used up previously. But the need for specific nutrients like proteins, vitamins, and minerals remained more or less the same. It is therefore evident that, unless the quality of our food improves very considerably, we are bound to have a distinctly inferior nutrition compared with that of the previous generation, so far as protective nutrients are concerned. This lower plane of nutrition might be one of the factors causing the craving for proteins and vitamins at the present time.—I am, etc.,

London, W.1.

Cost of T-piece Anaesthetic Technique

SIR,—I have waited for some time for someone to criticize Dr. John Bullough's article (January 5, p. 28) and perhaps you will accept this rather tardy rejoinder. Dr. Bullough does a service in pointing out that breathing against pressure may well increase venous bleeding, but his cure, to my mind, is a grossly extravagant one.

The technique he describes for a radical mastectomy relies largely on thiopentone anaesthesia, and can just as easily be carried out with an ordinary semi-open technique with a Heidbrink valve with no tension on the spring, thus offering practically no resistance to respiration and a total consumption of nitrous oxide and oxygen of 5 litres/min. Even better, such technique would be conveniently carried out with a flow of, say, 2 litres/min. of nitrous oxide, and about 400 ml./min. oxygen with the expiratory valve on no tension and an absorber in the circuit.

The difference between this and Dr. Bullough's technique would be 4 litres/min. of nitrous oxide; or 52.8 gallons per hour. That this is a serious matter in these hard times is obvious by the simple calculation that if all the anaesthetics in the Northampton General Hospital were given by this method it would cost £36 per week, or £1,872 per annum less in nitrous oxide than if done by the method Dr. Bullough suggests.

While one must be ever mindful of one's duty to the patient, and to give him of our best, extravagant techniques should not be used where there are reasonably economical alternatives.—I am, etc.,

Northampton.

F. F. WADDY.

Congenital Duodenal Obstruction and Mongolism

SIR,—We were very much interested in the paper by Drs. Martin Bodian, L. L. R. White, C. O. Carter, and J. H. Louw (January 12, p. 77) on the association of congenital duodenal atresia and mongolism. One of us (V. S.) saw a baby in 1948 with both conditions, and a further one in 1951. These babies were recognized as mongols and were not subjected to operation, the duodenal lesion being con-

firmed at necropsy. The second writer (M.C.) had seen a similar case in London in 1947, in which the duodenal lesion was confirmed at operation.

The combination of these two relatively rare conditions seems to us especially significant in so far as it may point to a limited interval of time, when the developmental abnormality leading to mongolism occurs.

Duodenal atresia probably results from a failure of the duodenum to recanalize during the fourth to seventh weeks of gestation. The septal defects unusually common in mongols result from a developmental aberration between the fourth and ninth weeks of foetal life.

Any attempt to explain the condition must also take into account the known rise in incidence of mongolism in the later years of the reproductive period. We feel that a detailed study of the early weeks of pregnancy in mothers over 40 years of age may possibly throw some light on the aetiology of mongolism.—We are, etc.,

Shortage of X-ray Films

SIR,—Following my recent inquiry made through the House of Commons and from the official reply which followed from the Board of Trade, I am informed that they hope to expand the manufacture of x-ray films by 74% during the current year. This to meet the present increased demand of 76% (since the year 1947), with at the moment a disastrous acute shortage in the home market, requires no further astonished remarks from me. The Board of Trade letter goes further and states that according to the Ministry of Health records only one hospital has suffered from the present disastrous shortage of x-ray films. They conclude by saying that the position is being watched. No, 74% increase will not do, but such is the continued toll of slow-moving officialdom and bureaucracy.

Surely here is an opportunity for a Government seeking new channels for export to expand rapidly the film industry and export, not only the 40% quota of films now going abroad, but perhaps greatly increase this figure, provided they meet first the needs at home. The industry backed by the Government could expand their plant quickly and so help the country in its present financial difficulties.

As one of the pioneers to introduce mass miniature radiography into this country I feel sure that to establish mass radiography as a form of economy is in itself largely a false economy and would have a very limited application in routine radiography owing to the shortcomings of the miniature film. For instance, it would be wrong to expect to detect, say, a very early osteomyelitis of a vertebra on a mass miniature film, but it could be used to record the rate of passage of a barium meal through the alimentary tract; not, however, for picking up fine detail such as minute ulcers in the stomach or duodenum which are sometimes barely detectable even on large-scale films.

Certainly it has its application and limitations in ordinary routine chest work. It seems to me that, as it has now become a wide practice in the Health Service for staff and also for emigrants going abroad to have routine x-ray examinations of chests, these people could quite easily be examined by mass radiography and if necessary go to centres for this purpose, and so again economizing in the number of mass radiographic machines in use. Subject to correction and according to available information, two Colonies only are using mass miniature radiography. Of the Canadian emigrants apparently 2,000 per month are mass radiographed. The Australians, approximately 7,000 per month, are also mass radiographed, except where disease of the lungs is known to be present, or in miners and others of similar occupation. South Africa and New Zealand, however, still insist on large-size films.

The time is now ripe for a deputation from one of our active radiological societies to visit the Board of Trade and enlighten them.—I am, etc.,

London, W.1.

NORMAN P. HENDERSON.

L-Noradrenaline as a Vasoconstrictor

SIR,—I was very much interested to read the article by Dr. H. C. Churchill-Davidson (December 29, 1951, p. 1551). I have used noradrenaline in about 10 cases—mostly gross hypotension after surgical operations in extremely ill patients. In one case only I used it after hexamethonium bromide; this also responded so well that I have reason to believe that noradrenaline and not methedrine is the answer to the dangerous fall of blood pressure which one sometimes gets after the administration of hypotensive drugs. On the other hand, I am inclined to stick to methedrine for fall of blood pressure to a low level under spinal analgesia, because of its ready means of administration and prompt results. Moreover, to maintain the blood pressure at a satisfactory level requires an infusion needing constant supervision and a very careful watch on the blood pressure.

The condition of the chest is one of the difficulties which appeared to me of real practical importance when using noradrenaline in dealing with hypotension in elderly people. It has been often necessary to continue the infusion drip for 24 to 48 hours, though at a slower rate, to get a sustained rise in the B.P. level, and in these cases the patients get a chest condition with bubbling and rattling throughout. I would like suggestions from others on this point. However, I am convinced personally that it gives a slow but sustained rise in the blood pressure as opposed to prompt but transitory actions of methedrine, etc. On the other hand, the complexity of administration and the danger that the drug, if injected as opposed to infused, might kill the patient at once may for some time keep this valuable drug in the background in comparison with the others in common use. May I in this connexion put forward a suggestion that the manufacturers supply ampoules containing 2 or 2.5 ml. and not 4 ml.? In most hospitals the intravenous infusions are carried out from bottles containing 540 ml. of blood, saline, glucose, etc., and only 2 ml. or often 2.5 ml. noradrenaline solution is given, the rest being wasted. The second dose from the open ampoule does not produce good results at all.—I am, etc.,

Manchester.

RASHBEHARI GHOSE.

Placing Lymph for Vaccination

SIR,—Professor Robert Cruickshank (January 26, p. 212, and February 2, p. 268) does not say anything about getting vaccination lymph on to the skin. This is important for the inexperienced doctor. He might find himself trying to vaccinate a person without a blower or with one that does not work. The fact that some do not work is guessed from the fact that Pye's *Surgical Handicraft* describes a home-made one—a teat from a baby's bottle. In case one has no blower the following method is good enough. The ends of the tube are broken off cleanly and the lymph shaken down to the end. By applying this end to the site enough lymph can be easily deposited without having to blow by mouth. Only a very small amount is necessary.—I am, etc.,

Heath Hayes, Staffs.

P. J. O'BRIEN.

POINTS FROM LETTERS

Penicillin and Colds

DR. ERNEST JONES (Elsted, Sussex) writes: Those who vaunt the abortive influence of penicillin with colds would do well to record also the sequelae. Recently I used a nasal insufflation of penicillin and sulphathiazole three times in the first 24 hours, and at the end of the next day all symptoms had disappeared. I thought I had come across the real magic and prepared to spread the good news. But wait. Four or five days later the symptoms returned without any detectable reinfection, and I was in for one of the most miserable attacks for years, with several days in bed. Those viruses that had eluded the penicillin extorted an ample revenge for their slain brethren.

KING GEORGE THE SIXTH

"Our Most Illustrious Doctor" *

Four times within not much more than half a century the nation has mourned the death of a much-beloved sovereign. During the previous 63 years the throne had only one occupant; Queen Victoria reigned for so long that she came to be regarded as a permanent institution rather than a mortal being. Edward VII and George V lived out, the one almost the Psalmist's span, and the other slightly beyond it. George VI might have looked forward to many years of happy and useful reign. No English sovereign has died in his fifties since the Stuarts, who were short-lived. The average age at death of our sovereigns since George I is 73. On the other hand, during the 800 years which separate Alfred the Great from Queen Anne, no king or queen lived to be 70, and only seven out of the 46 of them reached the age of 60; and the average age at death was 44. The gradual prolongation of human life covers kings as well as their subjects.

An added poignancy is given to the passing of George VI because of the troubled and catastrophic events of his time. When he opened his first Parliament the Speech which he delivered from the Throne promised measures of slum clearance, the improvement of housing, meals for boys and girls attending industrial centres, and the lowering of the age at which the blind were to receive pensions. The threat of war certainly was hanging over Europe, but at home all seemed set for social betterment, a trim passage to the Welfare State. This prospect must have rejoiced the King's heart because of that unusual experience of the working conditions of the people which had earned him the title of "the industrial Prince." But the tragic interruption of the war came before he had reigned for three years, and although the war itself in some respects quickened the pace of social reform it brought about also such impoverishment as postponed indefinitely the realization of the brighter hopes which had been entertained.

"Real Work and Merit"

Against such a background a king with more showy gifts and more dominating personality might have played a more dramatic part, but possibly a more disastrous one for his country. This quiet domestic King, who on the eve of his 41st birthday came unexpectedly into this overwhelming inheritance, was well matched with his hour. The late Viscount Dawson of Penn, whose last appointment was to the headship of their medical household after the abdication of Edward VIII, wrote in March, 1937, to Sister Black, who had nursed

George V, "The King and Queen are doing very well; they are basing themselves on real work and merit—and not on flairs."

People who were growing accustomed to a world in upheaval turned with relief to the King and his family, glad to feel that their titular head was someone like themselves—not a pompous emperor nor a swaggering dictator but one who preferred simple things, who smiled at the same jests, took pride in the same small achievements, claimed no particular genius to separate him from the common man, found his chief satisfaction in the home circle, and was, like his father, but not so like some previous occupants of the throne, the embodiment of themselves. He continued the pattern of life of George V. Archbishop Lang noted on receiving his first letter from the new King that his signature might have been taken for his father's. He was the same plain, direct, unassuming man. The industrial worker with whom he had talked during his hundreds of visits to factories, the boys with whom he had camped in summer holidays, the sailors with whom he had served in the first World War, found in him someone none the less kingly because he had the common touch.

It certainly seems as if the English people like a king who is a good family man. Even if they do not all practise the same virtues themselves they expect to find the example in their crowned heads. And so it has happened that the Throne is now more broadly based on popular affection and respect than ever it has been in the past. The hostility with which the Throne was regarded by not inconsiderable sections of the population in times gone by found no expression at all during the late reign. On the other hand, sycophancy, that unpleasant growth of courts, could not flourish in the presence of this modest and unpretentious ruler, so obviously unassuming and retiring, nor of his friendly and unaffected queen.

King George VI was not trained for the throne. He was not brought up, as he is reported once himself to have said, to be "palace minded." In fact, until his accession, he lived mostly in small houses. The worst training for a king is in the gilded cage where the heir apparent is imprisoned. King George when Duke of York took his full share of the duty and discipline which are imposed upon the general body of citizens—more so than most indeed, because, again like his father, his training was in the Royal Navy. He went to Osborne as a cadet, and then to Dartmouth, and afterwards came his service in the war of 1914-18. The service was interrupted by illness, but it included the Battle of Jutland. "In the *Collingwood*," he wrote, "[we] saw a good deal more than some of the other

*The form of toast given at dinners of London University schools.

ships, and we fired more than they did; but we were not hit at all, which was lucky, though we were straddled several times. One shell dropped over the fo'c'sle, missing us by inches."

The Industrial Prince

Towards the end of the war he served for a time in the Royal Air Force during its early period of organization, and then came the academic interlude of Cambridge, where he lived the life of the ordinary undergraduate, studying civics, commercial geography, and history, to which, when he became interested in industrial affairs, was added economics. His close acquaintance with industry began when he was made President of the Industrial Welfare Society. The idea behind that society as a means of bringing employers and workmen together was that of the Rev. Robert Hyde, who had worked for 15 years among the people of Hoxton and brought his experience to the Ministry of Munitions during the war. When he founded the society he secured the Duke of York as much more than an honorary president. The Duke at that time was a young man of 24, and it is reported that when asked to lead the enterprise he made the condition that there should be "none of that damned red carpet." He visited factories all over the country—150 of them in five years. The purpose was to explain employers and employed to one another. Particular stress was laid on physical training in industry, for which the help of the British Medical Association was sought. His greatest personal service to the country up to the time of his accession was given through that society. It represented a new departure in royal progresses, because, as Hector Bolitho says in his biography of the King, up to that time, although the Royal Family were noted for benevolence and had given their names to innumerable civic institutions, charities, and public services, there had been no personal link between them and the great masses employed in industry and transport, on whom, after all, the very life of the country depends.

The same idea of bringing classes together was behind the Duke of York's camps. As Duke of York, and for one year as King, he camped for the summer holidays with a company of boys, half of whom were drawn from public schools and half from industrial areas. In the course of 15 years something like 7,000 boys were his guests and shared with him the rough-and-tumble, the freedom and improvisation of camp life. Other like causes claimed his interest, such as the National Playing Fields Association. An organization with which he was closely identified was the British Empire Cancer Campaign. He presided over the annual meeting of that body at the House of Lords only a fortnight before his accession, and on that occasion mentioned the sympathy of his family with all work on the cancer problem, especially the interest taken in it by his father and mother and by his grandfather, Edward VII.

In 1933 he opened the International Paediatrics Congress, the first to be held in Great Britain, and reminded the assembly that there were people living who remembered the foundation of the first hospital for children. "Speaking as a father," he voiced the gratitude of parents far and wide. "Take care of the young and the country will take care of itself."

Another of King George's distinctions was as a traveller. Here again he followed the pattern set by his father. It is difficult to say which of them saw most of the British Commonwealth; both of them visited all the Dominions and other parts of the Empire as well. George V looked upon Empire tours for his sons as a part of their education, as they had been his own, much as the grand tour of the Continent had been to the "milords" of the eighteenth century. Both the late King and his father knew Britain overseas far better than any sovereign had known it before, and both of them appealed to the imagination of the peoples they encountered, white, or black, or brown, in much the same way.

His record as King, both during the war years and since, has been amply recalled in the daily press. If his interest in hospitals and medicine did not find so many outlets as his father's, it was none the less deep and sincere. Two occasions on which that interest was manifested in a special degree were his attendance at the celebrations of the 400th anniversary of the second founding of St. Bartholomew's Hospital in 1946 and the opening of the new building of the National Institute for Medical Research at Mill Hill in 1950. He became Patron of the British Medical Association within a few weeks of his accession. The speeches of princes on public occasions are usually formal and colourless. "As tedious as a king," says Dogberry. But King George, as might have been expected from a man of his methodical and painstaking nature, was said to make his own revisions and improvisations, sometimes continuing to revise until the moment of delivery. Up to the time he ascended the throne he had delivered over five hundred speeches in public.

Unfortunately he suffered from a disabling speech defect, inherited from his ancestors of the House of Brunswick—one of the most unhappy afflictions that can befall a man called to high office. It was the more grievous in view of the fact that broadcasting had made it possible for the voices of rulers and statesmen to be heard all round the world. With the help of an Australian speech therapist he made heroic efforts to overcome the disability, and, although his speech to the end remained slow, his later platform utterances and broadcasts were in marked contrast to his earlier ones, and showed how far he had succeeded in conquering the impediment.

The King's Illnesses

The King's life was chequered by frequent illness. He was a man of frail constitution, but with a real determination to make the best of it. The

testimony of his doctors was that he was an admirable patient, willingly submitting to irksome restrictions and co-operating completely in all measures of treatment. His various illnesses were never allowed to cause more than a minimum of interference with his duties. While he was a naval cadet at Osborne he had a severe attack of pneumonia. Soon after the beginning of the first world war, during his service in the Navy, he had severe dyspeptic symptoms and was taken from Scapa Flow in a hospital ship to Aberdeen. He went back again to play his part in the battle of Jutland, where he was second in command in the fore turret of his ship, but afterwards he returned to shore for less exacting duties, and eventually he was operated on in 1917 for duodenal ulcer. In the early part of his reign he had a severe attack of gastric influenza, which caused the abandonment of a number of engagements, including the opening of the Birmingham Hospitals Centre.

A more serious illness developed in 1948. In the late November of that year a bulletin announced that the King was suffering from obstruction to the arterial circulation in the legs. The bulletin, which was signed by the late Sir Maurice Cassidy, Sir Thomas Dunhill, Professor J. R. (now Sir James) Learmonth, and Sir John Weir, added that the strain of 12 such years of reign had appreciably affected his resistance to physical fatigue. After some days of rest, a reassuring bulletin stated that there had been an improvement in the general health of the King, which was an important factor in re-establishing the arterial circulation to the feet. It was also stated that the restoration was being encouraged by appropriate medicinal and physical means, but that it was a slow process, extending over a period of months. In the middle of December the re-establishment of the circulation in the left leg and foot had reached a stage sufficient to permit some activity, but in the right leg and foot it had been less rapid, so that only strictly limited activity, confined to indoors, could be undertaken. In March, 1949, the operation of lumbar sympathectomy was performed with a view to improving the blood supply in the right foot. The surgeons were Professor Learmonth and Professor (now Sir) J. Paterson Ross. The King made a good recovery, and a prolonged convalescence was undertaken in order to secure the continuation of the natural process of forming a collateral circulation which had been encouraged by the operation.

The King undertook a number of public engagements in 1950 and the early part of 1951, but those who saw him realized that he was evidently still a very sick man. Disease of the lung was first mentioned in a bulletin signed by Sir Daniel Davies, Sir Horace Evans, Dr. G. (now Sir Geoffrey) Marshall, and Sir John Weir, on June 1, 1951, when it was stated that the King was confined to his room with an attack of influenza, and that there was a small area of catarrhal inflammation in the lung. In the early autumn a visit of specialists to Balmoral was followed by the King's

sudden return to London to undergo treatment not possible in the Highlands. A later bulletin stated that structural changes had developed in the lung. On September 23 an operation for resection of the lung was performed; the following eight medical men were in attendance: Sir Daniel Davies, Dr. Geoffrey Marshall, Sir Robert Young, Sir Thomas Dunhill, Mr. C. (now Sir Clement) Price Thomas, Dr. R. Machray, Sir Horace Evans, and Sir John Weir. On October 8, after daily bulletins, it was announced that His Majesty continued to make satisfactory progress and that no further regular bulletins would be issued.

In his broadcast on the following Christmas Day, in a voice that bore witness to the weakness of his respiratory system, the King paid tribute to "the faithful skill of my doctors, surgeons, and nurses," and he sent a special donation to Westminster Hospital as a token of his gratitude to the medical and nursing staff who had gone from that hospital to the palace. The honour of knighthood was conferred upon two of the medical men concerned—Sir Clement Price Thomas and Sir Geoffrey Marshall.

"A True King"

The late King admirably filled the throne vacated by his brother. He maintained the constitutional tradition of the monarchy, and his strong sense of public duty and high standard of family life were an inspiration at a time when that sense of duty was becoming confused and those standards had been lowered. The deaths of sovereigns, as of other great persons, are the occasion invariably for much uncritical praise; then after a time there succeeds a more balanced estimate, and sometimes the satirists and detractors get to work (as in the case of Queen Victoria) in their not always laudable attempts to re-write history. The enduring monument to the late King's reign is the firm establishment of the constitutional monarchy in the hearts and minds of the people. He was a true King and a good man.

Chrysostom wrote in his *Tasks of Kingship*, "The clearest mark of a true king is that he is one whom all good men can praise without compunction, not only during his life but even after his death."

A MESSAGE OF SYMPATHY

After the announcement of the King's death in his sleep on February 6 the following telegram was sent to the Private Secretary at Buckingham Palace:

"The President and Members of the British Medical Association are deeply grieved at the death of their Beloved Patron the King and humbly offer heart-felt sympathy to Her Majesty the Queen and all members of the Royal Family. E. A. Gregg, Chairman of Council."

This telegram, addressed to the Chairman of the Council of the British Medical Association, was received in reply on February 8:

"I am sincerely grateful for your message. Please assure all those for whom you speak that I deeply value their kindness and sympathy. Elizabeth R."

Obituary

Dr. ALBERT VICTOR JOHN RUSSELL died at his home in Birkenhead on January 14. Born at Strabane, in Northern Ireland, in 1899, he was educated at the Methodist College, Belfast. He studied medicine at Dublin, and graduated M.B., Ch.B., B.A.O. in 1921, taking the L.M. (Rotunda) in the same year. He served as house-physician and house-surgeon at the Chester Royal Infirmary, house-surgeon at the Shropshire Orthopaedic Hospital, and house-physician at the Queen's Hospital for Children, Hackney. Subsequently he was a medical officer with the Cunard White Star Company and much of his service was in the old *Mauretania*. He entered general practice in Birkenhead in 1934 and was an assistant physician at the Birkenhead and Wirral Children's Hospital from 1934 to 1942 and physician from 1942 to 1948. He served in the Army during the last war, and later, following his recall because of shortage of doctors in Birkenhead, he joined the Home Guard and served as medical officer to the 4th Cheshire Battalion. From that time onwards he took an ever-increasing interest in medico-political matters and was a member of the panel committee and local medical war committee. He was elected chairman of the administrative committee of the Birkenhead Executive Council in 1947, vice-chairman of the Birkenhead and Wirral Division of the B.M.A. in 1950, secretary of the Birkenhead local medical committee in 1949, and a member of the Representative Body of the B.M.A. and a member of the Conference of Local Medical Committees in 1949. All these appointments he held until the time of his death. Dr. Russell was an able and conscientious worker on behalf of his colleagues, and was an extremely well-informed and active supporter of the British Medical Association. He was a classical scholar, and in addition a man of many and diverse interests, widely read on a variety of subjects. He is missed by many friends among his colleagues and patients in Birkenhead.—R. W. L. P.

Dr. WALTER HENRY POLLARD, who was in general practice in Birmingham for upwards of fifty years, died at his home in Birmingham on January 29, aged 84. He studied medicine at St. Bartholomew's Hospital, where he won the senior entrance scholarship in science. After qualifying in 1894 and graduating M.B. a year later, he worked in and near London for some years before settling in practice in Bearwood, near Smethwick. Later he moved to Edgbaston, where he remained until his death. Dr. Pollard was well known in the district not only because he was a respected general practitioner but because of his keen interest in local affairs. He was elected a member of the Smethwick Borough Council many years ago, and in due course he became a justice of the peace, and eventually mayor of Smethwick just after the first world war, during which he had served as medical officer to the auxiliary military hospital at Lightwoods Hall. Dr. Pollard was one of the first members of the Birmingham panel committee and was a vice-president of the Birmingham Medical Institute. Later he became chairman of the Birmingham Central Division of the B.M.A. (1931-2) and president of the Birmingham Branch (1936-8). For several years in the nineteen-thirties he represented his Division at the Annual Meeting. Although he gave up general practice about ten years ago, Dr. Pollard retained his post as chairman of No. 5 medical recruiting board in Birmingham until 1948.

Dr. MAX HARTMANN, the distinguished Swiss chemist, for long associated with Ciba Ltd., of Basle, died on February 2. Born at St. Gallen, Switzerland, in 1884, Max Hartmann obtained his doctorate in chemistry at Munich, shortly afterwards joined the Ciba laboratories, and, after a brief interval again at Munich, settled in 1915 for good with Ciba, where he entered the pharmaceutical department, then in its early stages of development. His subsequent researches led to

the production of many valuable medicinal products, of which "coramine" is probably the most widely known. Dr. Hartmann became an honorary member of the Swiss Chemical Society after long service as treasurer, received an honorary doctorate in medicine from the University of Basle and in technical science from the Swiss Polytechnical School, and became a member of the board of management of Ciba. He played a prominent part in the establishment of the Swiss Academy and very actively interested himself in the work of other foundations, such as those for chemical, biological, and medical scholarships, and the Swiss Tropical Institute. His last visit to London was to take part, with Sir Henry Dale and other distinguished men, in the opening ceremony of the Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research, when he paid tribute to "the long line of great British research workers, past and present." Those who knew Max Hartmann will not forget the kindness and the homely character of this man of rich personality. In his department there was no place for pettiness and jealousy, and, directing it with tolerance and understanding, Dr. Hartmann always gave the fullest credit and support to all his co-workers. His fine judgment and shrewd common sense made his advice highly valued beyond his department and beyond Ciba, not only in scientific matters and administration, and especially in the selection of staff, but also in the world of art. His aged mother and two children survive him.—G. E. W. W.

Dr. GRAHAM RENSHAW died after a short illness on January 13 at the age of 79. Educated at the Leys School, Cambridge, he graduated M.B., Ch.B. at Manchester University in 1899 and proceeded M.D. in 1914. Soon after qualifying he joined his father, Dr. Herbert Smith Renshaw, in practice in Sale, and when his father retired in 1916 he took complete charge. Graham Renshaw was a man of wide interests. A well-known naturalist, he wrote articles for a number of natural history journals, and from 1922 to 1924 owned and edited a monthly magazine called *Nature Lover*. At his home in Sale he kept a miniature zoo containing a variety of animals, birds, and fish. In 1940 he retired from general practice and went to live in Hale, but he continued his work as medical referee for a number of insurance companies till shortly before his death. He was of a friendly disposition and will be greatly missed by all who knew him. He is survived by his wife and daughter.—R. H.

The death occurred on January 11 of Dr. JOHN LEO MCSWEENEY at the early age of 48. He was the youngest son of Eugene McSweeney, of Cork, a prominent Irish educationist and sometime lecturer at University College, Cork. Leo McSweeney was educated at University College, Cork, and graduated M.B., B.Ch., B.A.O. at the National University of Ireland in 1926 in spite of being handicapped by the early onset of the illness from which he suffered throughout his professional career and from which he eventually died. The first five years after qualification he spent as a ship surgeon, and he then settled in general practice first at Ferndale in South Wales and finally, in 1938, in Birkenhead. Owing to his chronic ill-health his outside activities were limited, though he was keenly interested in sport, but he derived great consolation from his religion, being a very prominent member of the Roman Catholic community in Birkenhead. The esteem in which he was held by his patients was evidenced by a very large congregation at his requiem. He is survived by his widow, Sheila, daughter of the late Dr. T. McKelvie, of Cardiff, and his brother Dr. Christopher J. McSweeney, who is in consultant practice in Dublin.—E. G. W.

We record with regret the death at Newcastle-upon-Tyne on January 20 of Dr. ELDRED CURWEN BRAITHWAITE. He was born in Cumberland in 1885, and was educated at the University of Durham, where he graduated M.B., B.S. with first-class honours in 1909, taking the M.R.C.S., L.R.C.P. in the same year. In 1910 he took the D.P.H., and three years later proceeded M.S. He was elected F.R.C.S.Ed. in

1922. Dr. Braithwaite entered the Colonial Medical Service in 1911 and retired in 1944. For most of this period he served in West Africa, becoming senior specialist in Nigeria. He took part in the Cameroons campaign in 1914-16, was mentioned in dispatches, and received the thanks of the Secretary of State for the Colonies. He was appointed O.B.E. in 1936 and promoted C.B.E. in 1947.

Dr. H. R. MacK. Ferguson writes: A pupil of the late Rutherford Morison, Braithwaite specialized in surgery, and his work in Owassi, Nigeria, and other up-country stations, work of which I have first-hand knowledge, was of a very high order and of the greatest value to Africans, whom he served with devotion, and to the Colonial Government. Braithwaite was at his best when called upon to tackle some difficult surgical problem under almost impossible conditions. His cheery humour was the delight of his friends and a splendid tonic to countless patients.

Medical Notes in Parliament

Dentists' Bill in the Lords

In the House of Lords on February 5, Lord WOOLTON moved the second reading of the Dentists' Bill. He explained that the Bill was introduced to grant dentists the status and dignity of a self-governing profession, to regulate the admission of foreign and Commonwealth dentists to the dental register, and to provide for the training of ancillary dental workers. A new General Dental Council was to be set up, composed of 34 members, all but four being registered dentists. In addition, six members of the General Medical Council would act as members on the General Dental Council when matters concerning dental education were discussed. The visiting of dental schools, the registration of dentists, and disciplinary procedure would be transferred to the General Dental Council. The Bill gave a new right of appeal to the judicial committee of the Privy Council against a decision to remove a dentist's name from the register in the same way that that appeal had been given to a doctor in the Medical Act, 1950.

The only new principle introduced in the Bill empowered the General Dental Council to establish classes of ancillary dental workers. The public dental service for expectant and nursing mothers and young children was in serious need of additional manpower. In December, 1951, the equivalent of just over 700 full-time dental officers were employed on this work, whereas an adequate dental service for children would require some 2,800 full-time dentists. The number of dentists on the register was likely to increase, but slowly. Just before the war the annual entry into the profession was about 340; during the last five years between 600 and 650 students had entered dental schools each year. Expansion of the schools was costly and would be slow, and at the present rate of intake the number of 10,000 practising dentists in England and Wales would not be greatly increased. Meanwhile the public would have an insufficient dental service. The Bill would enable the General Dental Council to give official recognition to oral hygienists, but provided they should only work under supervision of a registered dentist. The Government was considering whether ancillary dental workers, able to undertake the extraction and filling of teeth, as in New Zealand, should also be introduced. The Bill provided that the Dental Council should arrange for the training and subsequent employment of a number of persons whose work would include extraction and filling, and that the Ministry of Health and Secretary of State for Scotland should be empowered to give financial help towards the cost of this experiment. A two-year training was envisaged, and after the first batch of dental workers had been employed for a year the council was to report on the experiment. If the results justified such action the council was authorized to proceed, in conjunction with the Privy Council, to draft regulations establishing such a class as ancillary workers.

Not Enough Dentists?

Lord TEVIOT said he did not agree that there were not enough dentists in the country to provide reasonable treatment for adult patients. When a moderate charge had been introduced for the supply of dentures the drop in the number of patients was most noticeable, and he believed that the new charge of up to £1 would make a large reduction in the number of patients seeking treatment. There was no doubt that the schools and children were alarmingly short of treatment and inspection. He contended that a dental surgeon rather than an ancillary worker should do the filling of a child's permanent teeth, but at the moment it barely offered a living for the dental surgeon to become a children's dentist. Parliament had to offer an inducement of a reasonable return for such work.

Lord WEBB-JOHNSON declared himself in favour of encouraging the training of dental nurses, provided the limits of their activities were narrower than was laid down in the Bill. The dental nurse should not be permitted to interfere with living tissues. The auxiliary workers could be made technically competent, but would not have sufficient training to make them competent to form a diagnosis, especially during the eruption of the second teeth. Lord AMULREE endorsed the plea for the foreign refugee dentists at present working in this country, and Lord MANCROFT hoped that the misgiving concerning ancillary workers would disappear. He dissented from the description of the auxiliary workers as partially trained. It was not right to describe a hospital sister as partially trained. She was trained to do her own job.

Lord HADEN-GUEST said the London County Council at present ought to have 66 dentists but had only 38. The deficiency in dental establishment amounted to a disaster which could not be made up. He was not convinced that, because of the charges now to be made for various dental services, dentists would go back to the school dental service. He believed that the setting up of a service of ancillary dental workers under the personal supervision of dentists would be valuable.

The Bill was read a second time without a division.

Milk for 5-year-olds

Mr. WILLIAM IRVING regretted on January 31 that the Ministry of Food and the Ministry of Education could not agree about supplying milk to schoolchildren. The Ministry of Food denied further responsibility when children reached the age of 5 and, if the education authorities who became responsible for the education of children at that age had no places in the schools for the children, those children could not get free milk. About 15,000,000 gallons of milk were consumed by schoolchildren each year (about twice the pre-war figure), and this was a good investment. The problem ought to be a simple one—if children at the age of 5 could not be provided with education they should be provided with school milk in the same way that schoolchildren were provided with it during the holidays. Mr. KENNETH PICKTHORN, for the Ministry of Education, agreed that the matter deserved attention. It was not true that the Ministry of Education became automatically responsible for children on their reaching the age of 5. The subject they were discussing was a gap of a few weeks, or at most of not many months. Most children were in attendance at school before they were 5 years and 1 month old. If the Minister allowed children who were not practically in attendance at school to be put nominally on the register in order to receive milk it would not only be a breach of the Statute but also a fraud upon the Ministry of Food. To continue the child's ration book so that until it was absorbed in the school machine it could receive cheap milk, orange juice, and the rest would have meant giving benefits worth 3d. and 4d. a week instead of 10d. worth of milk, and could not be done by administrative fiat. The simple truth was that neither the Ministry of Food nor the Ministry of Education had been able to find a means by which the thing could be done. If it were done, the effort and expense would be out of proportion to the benefits secured.

Industrial Injuries

In the House of Commons on February 4 Mr. BARNETT JANNER drew attention to the grave loss of life and health from industrial injuries and diseases. He said the report of the Ministry of National Insurance for November, 1951, gave the number of awards of Industrial Deaths Benefit as about 3,000 in 1949 and approximately the same in 1950. The position might deteriorate. Increased mechanization was being introduced in mining and quarrying, and machinery accounted for most of the accidents. He asked the Government to see that there was constant consultation between the departments which dealt with this problem. Sir PETER BENNETT, replying for the Ministry of Labour, said prevention of industrial accidents was primarily a matter for employers and employed. The Ministry always urged managements to appoint men specially devoted to safety work, and was arranging for special lectures to be given by factory inspectors in universities and technical schools. The setting up of an additional committee on the subject would be a waste of time.

Prescription Charge Exemption

Mr. H. F. C. CROOKSHANK on February 5 declined to exempt old-age pensioners from payment of 1s. for their prescriptions unless they already received a public assistance grant or were otherwise unable to meet the charges without hardship.

Pensions for Cancer.—About 1,400 awards of pension have been made in respect of disablement or death from cancer accepted by the War Office as attributable to or aggravated by service in the armed Forces during the 1939-45 war and since. Information in respect of the 1914-18 war is not available.

Schools for Epileptics.—Miss F. HORSBRUGH is anxious to increase the provision for epileptic children in special schools. Approved-school boys and girls under 16 who suffer from major epilepsy are placed in special schools. When they cannot be so placed they usually have to be discharged to their own homes.

Suicides.—Suicides in prison in England and Wales were 10 in 1949, 3 in 1950, and 8 in 1951.

Poliomyelitis.—In 1948-51 35.5 cases of poliomyelitis per 100,000 of the population were notified in Scotland and 41.6 per 100,000 in England and Wales.

Hearing-aids and Wigs.—During one year the issues were 93,454 and 9,750 respectively. The estimated cost excluding overheads was £329,000 and £124,000.

Hospital Reports.—In Scotland hospitals are not authorized to charge for copies of reports taken from their records.

Crematoria.—No authorizations to build crematoria were given in the years 1945 to 1949; one was given in 1950 and three in 1951. There are 59 crematoria in England, Scotland, and Wales.

Universities and Colleges**UNIVERSITY OF ABERDEEN**

Dr. Ian Milne Richardson has been appointed Lecturer in Social Medicine in the University.

UNIVERSITY OF MANCHESTER

Professor Walter Schlapp has been appointed Dean of the Medical School for 1952.

Dr. E. L. Patterson and Dr. F. A. Langley have been appointed Senior Lecturers in Anatomy and in Special Pathology, respectively, and Dr. Basil Wolman, previously Assistant Lecturer in Child Health, Honorary Clinical Lecturer from December, 1951.

Miss Rose Heilbron, Q.C., will deliver the Margaret Ashton Memorial Lecture on "Women in the Professions" at the University on Friday, March 21, at 5 p.m.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following were admitted to the Membership of the College on February 1: R. C. Desai, E. G. Fox, J. P. R. Rees.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending January 26 (No. 4) and corresponding week 1951.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.

† Includes primary and influenzal pneumonia.

§ Includes puerperal pyrexia.

‡ See "Census Changes" overleaf.

Vital Statistics

Infectious Diseases

The chief features of the returns of infectious diseases in England and Wales during the week ending January 26 were increases in the number of notifications of whooping-cough by 224, dysentery by 113, and scarlet fever by 82.

The largest increases in the incidence of whooping-cough were Yorkshire West Riding 62, Gloucestershire 38, and Durham 37. The only variation of any size in the local trends of scarlet fever was an increase of 42 in Essex. The number of notifications of measles have been practically constant for the last three weeks, and the notifications during the week reviewed were only 9 more than in the preceding week. The only large fluctuations in the local trends of measles were a decrease of 104 in Cheshire and an increase of 66 in Staffordshire. The notifications of diphtheria were 5 more than in the previous week. Almost two-thirds of the notifications of diphtheria were returned by three counties—Lancashire 6, Yorkshire West Riding 5, and Staffordshire 5.

Notifications of acute poliomyelitis were 7 fewer for paralytic and 1 fewer for non-paralytic cases than in the preceding week. The largest returns were Lancashire 5 (Manchester C.B. 2); Gloucestershire 3 (Cheltenham M.B. 2); Kent 3; Yorkshire West Riding 3.

For the fourth consecutive week a rise has been recorded in the number of notifications of dysentery. A further 65 cases were notified in the outbreak in Norwich C.B., an increase of 13 on the total of the preceding week. The outbreak in this city began during the week ending November 24 with 25 notifications. In the next two weeks 117 and 200 cases were notified, and a steady fall occurred in the next five weeks to reach 31 cases in the week ending January 12, but in the succeeding two weeks a small rise has been reported. In the past ten weeks 788 cases have been notified in this city. Other large returns during the week reviewed were Lancashire 64 (Lancaster M.B. 11); Middlesex 44 (Willesden M.B. 17); Surrey 43 (Malden and Coombe M.B. 35); Devonshire 39 (St. Thomas R.D. 14, Exeter C.B. 13); London 38; Kent 31 (Beckenham M.B. 16); Yorkshire West Riding 29; Southampton County 26 (Portsmouth C.B. 24); Warwickshire 17 (Coventry C.B. 11); Denbighshire 15 (Ruthin R.D. 15).

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1942-50 are shown thus ————, the figures for 1951 and 1952 thus ————. Except for the curves showing notifications in 1951 and 1952, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending February 2

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,320, whooping-cough 2,652, diphtheria 24, measles 3,386, acute pneumonia 1,005, acute poliomyelitis 25, dysentery 490, paratyphoid fever 6, and typhoid fever 5.

Census Changes.—Population figures obtained at the 1951 census show that there are now 160 great towns (population over 50,000) in England and Wales instead of 126, and 17 principal towns (population over 30,000) in Scotland instead of 16. Therefore the 1952 figures for deaths, births, and stillbirths in these countries, published weekly in our Table, cannot be accurately compared with those for 1951, which are printed in italics. The 160 great towns in England and Wales have a population about 10% higher than the 126.

The Hospital for Sick Children in Great Ormond Street, London, W.C.1, has started its own periodical, which appears twice yearly, in June and December, at 7s. 6d. an issue. *Great Ormond Street Journal* publishes only the work of present or past members of the staff, and includes a sizable review of "laboratory diagnosis of virus and rickettsial infections" in its first issue, and of "paper chromatography" in its second (December, 1951), as well as shorter articles on such subjects as abdominal pain in childhood, and numerous case reports and special investigations. The journal is produced by H. K. Lewis and Co., Ltd.

Medical News

Silvester Traced.—Immediately after a request (*Journal*, January 26, p. 227) for information about the possible existence of a portrait of Dr. Henry Robert Silvester, Dr. F. C. Doble kindly telephoned to say that for many years one had hung in the house of the late Reverend Paul Silvester, of Land's End and Penzance. He suggested it might have passed to Mr. J. Allon Tucker, of Bath, a brother-in-law of Silvester, and through Mr. Tucker's kind permission we have been able to photograph the portrait,

Cyril Howe Studios, Bath

which is here reproduced. Silvester, the son of Dr. T. H. Silvester, was born in 1829, qualified M.R.C.S. in 1853, M.B. in 1854, and M.D.(London) in 1855. His paper on "A new method of resuscitating still-born children, and of restoring persons apparently drowned or dead" appeared in the *British Medical Journal* of July 17, 1858, at page 576. Silvester's method consists in placing the patient in the supine position, putting the arms firmly over the head to raise the ribs, and keeping them there until air ceases to enter the chest; the arms are then brought down to the chest and pressed against it for a second or so after air ceases to escape. This formula is repeated 16 times in a minute. In 1861 Silvester became honorary medical assistant to the Royal Humane Society, which awarded him the Fothergill gold medal in 1883. He died in 1908.

East African Blind.—A campaign for the 150,000 blind people in East Africa is being launched simultaneously in this country and in the East African territories this month. A committee headed by Sir John Hathorn Hall, until lately Governor of Uganda, has been set up by the British Empire Society for the Blind to make an appeal to firms with interests in East Africa. In Kenya and Uganda committees have been formed with the assistance of the Governments, and they are planning to raise £75,000 to provide funds for medical research into the causes and incidence of blindness and eye diseases, the provision of new or extended schools for the blind, demonstration teams, and aftercare facilities.

A committee is also being formed in Tanganyika, where a sum of £24,000 will be required to carry out a similar scheme. The British Empire Society for the Blind is co-operating with the Zanzibar Voluntary Welfare Society to raise a fund for blind welfare work. The money raised by the United Kingdom committee will help forward the plans made by the four territories.

Careers in the Colonial Service.—The Stationery Office has just published, at 3s. 6d., a useful guide to *Appointments in His Majesty's Colonial Service* which gives full information on all the many occupations, medical, nursing, veterinary, scientific, etc., the Service includes. Conditions of service, pay, eligibility, methods of selection, and further training after selection are described for all the different territories.

North of England Obstetrical and Gynaecological Society.—The annual general meeting of the society was held in Manchester University on Friday, January 25. The following officers were elected for 1952: president, Mr. P. Malpas; treasurer, Dr. C. H. Walsh; general secretary, Dr. T. E. Lennon; reporting secretary, Mr. S. Bender. Dr. B. Dodd described four cases of recurrent placenta praevia; Dr. T. Fitzgerald described a case of pregnancy in a septate uterus simulating angular pregnancy; and Dr. H. Doberman described two cases of malignant ovarian tumours in pregnancy. Mr. S. Bender read a paper on twin pregnancy.

Prizes for Amateur Medical Films.—A prize of 100,000 francs (£100 approx.), which might be divided, and several other prizes are offered by *La Presse Médicale* for the best 16-mm. silent or talking films made by an amateur for medical or surgical teaching. No film subsidized by or made by a laboratory or a firm is eligible, and both cinematic quality and teaching value will be judged. For full information, and entries, send to Secrétariat de La Presse Médicale, Librairie Masson, 120, Boulevard St. Germain, Paris 6^e, before March 1. Prizes will be presented in the Large Theatre of the Faculté de Médecine de Paris on April 4 at 8.30 p.m.

The "Pink Reports" are Back.—Most of the Industrial Health Research Board reports, familiarly known as "Pink Reports," have been out of print for some years. The demand for some of them has, however, continued, and it has now been decided that these should be reprinted. Three titles are now on sale again at the Stationery Office. No 34, *A Contribution to the Study of the Human Factor in the Causation of Accidents*, by E. M. Newbold; No. 61, *The Nervous Temperament*, by Millais Culpin and May Smith; and No. 77, *Fatigue and Boredom in Repetitive Work*, by S. Wyatt and J. N. Langdon (assisted by F. G. L. Stock). Others will follow in due course.

Liberian Tropical Medicine Institute.—The American Foundation for Tropical Medicine, in co-operation with the Harvard Medical School, in 1944 carried out a very successful investigation into all phases of human trypanosomiasis in Liberia, and this led Mr. Harvey S. Firestone, jun., to create a fund of \$250,000 enabling the foundation to build a permanent institute for research in tropical diseases. The institute has been set up at Harbel, which is about 50 miles inland in Liberia and the site of one of the two large Firestone rubber plantations. On January 11 it was opened by Dr. Thomas Mackie, the foundation's president, and the director is Dr. Thomas C. Burch; a small staff is now in residence and research work is beginning.

Foreign Decoration.—The King of Iraq has conferred the Insignia of the Order of Al Rafidain, Class III, on Lieutenant-Colonel W. R. M. Drew, O.B.E., R.A.M.C., in recognition of valuable services rendered by him as Professor of Medicine at the Royal College of Medicine at Bagdad.

Emergency Bed Service: Applications and Admissions.—During the seven days ending February 11 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,209, of whom 85.52% were admitted.

COMING EVENTS

Eugenics Society.—The Galton Lecture arranged for February 15 has been postponed until April 4.

Course on Frustration and Fulfilment.—The Davidson Clinic, Edinburgh, will hold an Easter school from March 26 to April 1. Lectures will be given by Dr. W. Rushforth, Dr. W. P. Kraemer, and other members of the staff; the guest speaker will be Dr. Margaret Lowenfeld. Tickets for the course cost £3 3s., and those wishing to attend are requested to apply as soon as possible, not later than February 28, to the secretary, 58, Dalkeith Road, Edinburgh, 9, who will supply full details.

Conference on the Mentally Handicapped.—The National Association for Mental Health is holding its annual conference at Bedford College, Regent's Park, N.W.1, from March 27 to 29. An inclusive ticket admitting to all sessions costs £1 5s. 6d. A full programme may be obtained from the conference secretary, 39, Queen Anne Street, W.1.

Institute of Almoners.—The annual general meeting will be held on March 28 at 6 p.m. in the Great Hall, B.M.A. House. Miss Hornsby-Smith, M.P., will address the meeting.

Lay Course in Tropical Hygiene.—The annual course for laymen will be held at the Ross Institute this year from July 14 to 18 inclusive. The course is arranged so that the morning sessions provide a continuous course on malaria and its control, and in the afternoons other tropical diseases and problems are dealt with, such as hookworm, bilharzia, nutrition, housing and sanitation, and protection against heat. It is intended for such people as estate and mine managers and their assistants, missionaries, and all those whose work in the Tropics makes them responsible for the health and welfare of others. There is no fee for the course. The names of those proposing to attend should be sent as soon as possible to the organizing secretary at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1, from whom full details may be obtained.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Saturday

BIOCHEMICAL SOCIETY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., February 16, 11 a.m., 305th meeting. Symposium: "Lipid Metabolism."

Monday

MEDICAL SOCIETY OF LONDON. 11, Chandos Street, Cavendish Square, W.—February 18, 8.30 p.m., "The Surgery of the Heart and Great Vessels," First Lettsomian Lecture by Mr. R. C. Brock.

Tuesday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 19, 5.30 p.m., "Chemical Aspect of Antibiotics," by Sir Robert Robinson, O.M., F.R.S.

CHADWICK TRUST.—At Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, London, W., February 19, 2.30 p.m., "How Improvement of Housing is Promoted in Belgium," Chadwick Public Lecture by Dr. J. Goossens (Brussels).

● **INSTITUTE OF DERMATOLOGY,** Lisle Street, Leicester Square, London, W.C.—February 19, 5.30 p.m., "Parapsoriasis and Poikiloderma Atrophicum Vascular," by Dr. P. D. Samman.

INSTITUTE OF PHYSICS: ELECTRONICS GROUP, 47, Belgrave Square, London, S.W.—February 19, 5.30 p.m., "The Mechanism of Radiation-Induced Chromosome Mutation," by Dr. J. M. Thoday.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At North Middlesex Hospital, Silver Street, Edmonton, N., February 19, 3 p.m., general meeting; demonstration of clinical cases, etc.; 4.45 p.m., "A Syndrome Resembling Haemophilia Due to a Circulating Anticoagulant," by Dr. I. S. Collins.

SOUTH WEST LONDON MEDICAL SOCIETY.—At Bolingbroke Hospital, Wandsworth Common, London, S.W., February 19, 8.30 p.m., "Analgesics and Sedatives," by Dr. H. C. Stewart.

WEST END HOSPITAL FOR NERVOUS DISEASES, 40, Marylebone Lane, London, W.—February 19, 5.30 p.m., neurological demonstration by Dr. N. G. Hulbert.

Wednesday

CAMBRIDGE UNIVERSITY.—At Department of Physical Chemistry, Free School Lane, Cambridge, February 20, 12 noon, "Some Aspects of the Physical Chemistry of Amino-acids, Peptides, and Proteins," by Professor John T. Edsall (Harvard University).

● **INSTITUTE OF DERMATOLOGY,** Lisle Street, Leicester Square, London, W.C.—February 20, 5.30 p.m., "Mycology—Treatment of Fungus Infections," by Dr. R. W. Riddell.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., February 20, 4.30 for 5 p.m., "Radiotherapy of the Genito-Urinary Tract," by Dr. J. R. Ivey.

LONDON UNIVERSITY.—At Institute of Education, Malet Street, London, W.C., February 20, 5.30 p.m., "The Physics and Chemistry of Molecular Interactions at Interfaces, with Special Reference to Haemolysis, Lipo-protein Associations, Fat Emulsion Systems, and the Possible Mode of Action of Some Biologically Active Molecules," special university lecture by Dr. J. H. Schulman.

ROYAL MICROSCOPICAL SOCIETY, Tavistock House South, Tavistock Square, London, W.C.—February 20, 5.30 p.m., film: "Behaviour of Cells of a Chemically Induced Rat Tumour in Tissue Culture," to be introduced by Dr. Charity Waymouth.

Thursday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 21, 5.30 p.m., "Recent Light on Mammary Function," by Professor H. D. Kay, D.Sc., F.R.S.

DONCASTER MEDICAL SOCIETY.—At Danum Hotel, Doncaster, February 21, 7 for 7.15 p.m., annual dinner and dance to be held in conjunction with Doncaster Division, B.M.A.

EDINBURGH CLINICAL CLUB.—At B.M.A. Rooms, 7, Drumsheugh Gardens, Edinburgh, February 21, 8 p.m., "Some Observations on the Use of the Antibiotics," by Dr. D. M. F. Batty.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY, The Union, University Avenue, Glasgow.—February 21, 7.30 p.m., address by Professor Dugald Baird.

● **INSTITUTE OF CHILD HEALTH,** Hospital for Sick Children, Great Ormond Street, London, W.C.—February 21, 5 p.m., "Patent Ductus Arteriosus and Pulmonary Stenosis," by Mr. T. Holmes Sellers.

LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—February 21, 8 p.m., ordinary meeting. "Myasthenia Gravis," by Professor Andrew Wilson.

LONDON UNIVERSITY.—Institute of Education, Malet Street, London, W.C., February 21, 5.30 p.m., "The Physics and Chemistry of Molecular Interactions at Interfaces, with Special Reference to Haemolysis, Lipo-protein Associations, Fat Emulsion Systems and the Possible Mode of Action of Some Biologically Active Molecules," special university lecture by Dr. J. H. Schulman.

MANCHESTER MEDICAL SOCIETY.—At Large Anatomy Theatre, Medical School, Manchester University, February 21, 4.30 p.m., "The Art of Feeling the Pulse," University Lecture on the History of Medicine by Dr. W. Evan Bedford.

ROYAL ARMY MEDICAL COLLEGE.—At Lecture Theatre, John Islip Street, London, S.W., February 21, 5 p.m., "The Neurology of the Cervical Spine," by Dr. W. Russell Brain, P.R.C.P.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—February 21, 5 p.m., "Carotid-Cavernous Aneurysms and Pulsating Exophthalmos," Hunterian Lecture by Professor S. P. Meadows.

ROYAL MEDICAL SOCIETY.—At Assembly Rooms, Edinburgh, February 21, 8 p.m., annual ball.

ROYAL SOCIETY, Burlington House, Piccadilly, London, W.—February 21, 10.30 a.m., "Excitation and Inhibition," discussion to be opened by Professor J. C. Eccles, F.R.S. (University of Otago).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At 26, Portland Place, London, W., February 21, 7.30 p.m., ordinary meeting. Symposium: "Insecticides," to be presented by Professor P. A. Buxton, F.R.S.

ST. ANDREWS UNIVERSITY.—At Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, February 21, 5 p.m., "The Management of Massive Gastro-duodenal Bleeding," by Professor F. H. Bentley.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—February 21, 4.30 p.m., lecture-demonstration in neurology.

UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—February 21, 4.45 p.m., "Mitochondria and Biological Oxidations and Phosphorylations," by Dr. A. L. Lehninger (Chicago).

WREXHAM AND DISTRICT CLINICAL SOCIETY.—At Wynstay Arms Hotel, Wrexham, February 21, 7.30 p.m., "Comparisons in Reproduction," by Mr. Owen Jones.

Friday

FACULTY OF RADIOLOGISTS.—At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., February 22, 2.15 p.m., Radiodiagnosis Section Meeting. "The Lateral Position in Chest Tomography," by Dr. George Simon; "Carcinoma of the Middle Lobe Bronchus," by Dr. G. Brian Locke. (Date changed from February 15.)

- INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 22, 5.30 p.m., "Reiticulosos," clinical demonstration by Dr. P. D. Samman.
- INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 22, 5.30 p.m., "Medical Aspects of Patent Ductus Arteriosus and Coarctation," by Dr. Graham Hayward.
- INSTITUTE OF PHYSICS: INDUSTRIAL RADIOLOGY GROUP, 47, Belgrave Square, London, S.W.—February 22, "The Chemistry of Radiographic Film Processing," by Mr. A. J. Axford.
- MANCHESTER MEDICAL SOCIETY.—At Large Anatomy Theatre, Medical School, Manchester University, February 22, 4.30 p.m., "Steroid Hormones and Behaviour, Experimental and Clinical Aspects," by Professor Klein (Strasbourg).
- OXFORD UNIVERSITY.—At Magdalen College, Oxford, February 22, 5 p.m., "The Neurophysiological Basis of Mind," Waynflete Lecture by Professor J. C. Eccles, F.R.S.
- ROYAL SANITARY INSTITUTE.—At Y.M.C.A. Hall, Talbot Road, Port Talbot, February 22, 10 a.m., papers: "Housing Progress and Development at Port Talbot," by Mr. G. V. Griffiths, A.M.I.C.E.; "The Health and Local Authority Services and the Population Problem," by Dr. D. J. Davies; "Housing Repair Difficulties," by Mr. G. A. Morgan. Afternoon visits.
- UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—February 22, 5.30 p.m., "Some Recent British Contributions in the Field of Pharmacotherapeutics," by F. Bergel, D.Sc.

APPOINTMENTS

Dr. G. A. Macgregor has been appointed an Official Member of the Legislative Council of the Colony of Aden.

GORDON, E. H., M.D., D.P.H., Assistant County Medical Officer and Medical Officer of Health, Urban Districts of Mansfield, Woodhouse, and Warsop, Nottinghamshire.

GRAHAM, H. A., M.D., F.R.C.S.Ed., Medical Officer (Consultant), Fitness Centre, Bridge of Earn Hospital, Perthshire, Eastern Regional Hospital Board (Scotland).

HERBERT, GLADYS M., M.R.C.S., L.R.C.P., D.P.H., Medical Officer of Health, Llandilo Health Division, and Assistant County Medical Officer, Carmarthen.

HORTON, E. H., M.B., B.Ch., T.D.D., Deputy Medical Superintendent (S.H.M.O. Grade), Glan Ely Hospital, Cardiff, Welsh Regional Hospital Board.

KERSHAW, J. B., M.B., D.P.H., Assistant County Medical Officer, and District Medical Officer of Health, East Sutherland.

MAIR, ALEX., M.D., D.P.H., Senior Lecturer, Department of Public Health and Social Medicine, University of St. Andrews; Consultant and Medical Adviser to the Almoner Service, Eastern Regional Hospital Board, Scotland.

PIERCE, J. W., M.D., M.R.C.P., D.M.R.D., Consultant Radiologist (Diagnostic), The Hospitals for Diseases of the Chest, London.

SOUTH-WESTERN REGIONAL HOSPITAL BOARD.—Senior Registrar in Psychiatry to Bristol Clinical Area, K. W. Aton, M.B., Ch.B., D.P.M. Paediatric Registrar, Southmead Hospital, Bristol, N. T. Jacob, B.M., B.Ch., M.R.C.P., D.C.H.

WATT, DAVID C., M.D., D.P.M., Consultant Psychiatrist, St. John's Hospital, Stone; Royal Bucks Hospital; and Stoke Mandeville Hospital, Aylesbury, Bucks.

WILSON, J. NOEL, Ch.M., F.R.C.S., Consultant Traumatic and Orthopaedic Surgeon, Cardiff United Hospital and Welsh Regional Hospital Board.

BIRTHS, MARRIAGES, AND DEATHS

DEATHS

Begbie.—On January 31, 1952, at a hospital, Glasgow, Ralph Stockman Begbie, M.D., M.R.C.P.Ed., D.P.H., D.T.M.&H., of 23, Carrick Road, Ayr, late of Hong Kong.

Boden.—On January 29, 1952, at 2, Methuen Park, London, N., John Smedley Boden, O.B.E., M.B., B.S.

Bodington.—On February 5, 1952, at a nursing-home, Winchester, Arthur Eaton Bodington, M.D., aged 87.

Cormack.—On January 31, 1952, at Mossiel, Felpham, Sussex, Harry Slater Cormack, M.C., M.B., F.R.C.S.Ed., Lieutenant-Colonel, I.M.S., retired.

Fischer.—On January 26, 1952, at Dunmore, Bo'ness, West Lothian, Nicolas Christian Fischer, M.B., Ch.B.

Fraser.—On February 7, 1952, at a nursing-home, Hove, Charles Fraser, M.D., D.P.H., of 5, The Drive, Hove, Sussex, aged 79.

McLaren.—On January 29, 1952, at his son's home, Felixston, Zululand, Natal, South Africa, Donald James McLaren, M.B., Ch.B.

Miller.—On January 26, 1952, at Cairo, William Sloan Miller, M.B., Ch.B., Surgeon Commander, R.N.

Moore.—On January 28, 1952, William Struthers Moore, M.B.E., M.D., of 7, Church Hill, Purley, Surrey.

O'Neill.—On February 2, 1952, Charles Sefton O'Neill, O.B.E., M.D., D.P.H., of Inglenook, Hale, Cheshire, aged 70.

Pearson.—On January 31, 1952, at 87, Bickenhall Mansions, London, W., John Sidnev Pearson, M.D., aged 75.

Scott-Dickson.—On January 29, 1952, at 9, Bruce Road, Dundee, Margaret Scott-Dickson, M.B., Ch.B., D.P.H., formerly of St. Andrews.

Strahan.—On January 28, 1952, at Winchester, Stuart Séguin Strahan, M.R.C.S., L.R.C.P., of Stacey's, Bentley, Hants, late of Hong Kong.

Thornton.—On January 29, 1952, at Shepherds Hill, East Knoyle, Salisbury, Wilts., Gerald Earl Thornton, M.B.E., M.B., B.Ch., aged 68.

Wallis.—On January 26, 1952, at Jersey, Channel Islands, Preston Richard Wallis, L.S.A.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Analgesia for Urethral Instrumentation

Q.—What is the best way of rendering the male urethra analgesic before instrumentation? Are there any special dangers to be guarded against? Please suggest suitable sources of further information on this subject.

A.—Analgesia of the male urethra is obtained by instilling the chosen solution in sufficient quantity to distend the anterior urethra, and then massaging it back into the posterior urethra. The best syringe to employ is a rubber-bulb type (Canny Ryall or Riches's urethral syringe). After the injection of 1 oz. (28.4 ml.) of the solution the urethra is closed by compression between the left thumb and forefinger or by a penile clamp, and with the fingers of the right hand the fluid is coaxed back into the posterior urethra by gentle but firm strokes. Little should escape when the compression is released. If the whole process is repeated after 5 minutes analgesia is more complete.

Many solutions are in use: cinchocaine hydrochloride 1/1,000 is very satisfactory, as is procaine hydrochloride 4%. Cocaine hydrochloride with sodium bicarbonate in 1/2 solution freshly made is also employed; stronger solutions are sometimes toxic and may be dangerous. Many of the newer analgesic agents can be used, but it is advisable to get to know the effects of one. Care should be taken not to inject air, and if the urethra has been injured by previous attempts at instrumentation some other form of anaesthesia is preferable. Full details of the methods are given in *Cystoscopy and Urography*, by Macalpine (John Wright and Sons, Bristol, 1949), and in *Essentials of Urology*, by Ainsworth-Davis (Blackwell Scientific Publications, Oxford, 1950).

Fits for Diagnosis

Q.—For the last 10 months a girl of 7 years has suffered from curious convulsive "fits," invariably induced by her bowel action. When entering the fit she strokes and plucks her hair, fixes her eyes glassily, licks her lips, emits a grunt, and moves her arms slowly about, with her fingers constantly flexing and "pill-rolling." She is pale throughout. There is no attempt to fall, bite her tongue, or froth at the mouth. She has an enormous appetite, and if thwarted will seek scraps even from the floor. She crams her food into her mouth, filling the whole cavity, but it is all digested when it comes through. She was successfully treated for threadworms some six months ago. There is no loss of weight. What is the differential diagnosis, and how should she be treated?

A.—Assuming that there are no abnormal physical signs, the account of the attacks suggests that the patient is suffering from either psychomotor epilepsy or spontaneous hypoglycaemia due to excess secretion of insulin by an adenoma of the islets of Langerhans. With the first, a full family history and an electroencephalogram might be helpful in diagnosis together with a therapeutic trial of phenobarbitone and sodium phenytoin. It seems important to exclude the possibility of hyperinsulinism in this patient, and the critical test is an estimation of the blood sugar level during an attack. If the level is below 50 mg.% and if the patient recovers rapidly following intravenous administration of glucose, it is very probable that an insulin-secreting islet-cell tumour is present in the pancreas. The fact that she has an "enormous" appetite is rather in keeping with this second diagnosis.

Gastric 'Flu'?

Q.—*I have a patient who has had 'flu five times in the last year. The duration is one or two days; intestinal signs predominate, with temperature and odd pains in the head and limbs. Recovery is completely without asthenia in four days. Blood smear is normal. He is incapacitated from his work for three days and resents this. What is the likely diagnosis? Is there any method of prevention?*

A.—It would be tempting to give this syndrome the label "gastric 'flu,'" but such a diagnosis is to be deprecated, for too often it masks some specific intestinal infection like bacillary dysentery or salmonella food-poisoning. The question does not state the age of the patient, what the "intestinal signs" are, whether catarrhal symptoms are present, or at what season of the year these attacks occur. The occurrence of "influenza" in the summer months should raise suspicion of a tuberculous infection. If headache and catarrhal symptoms are prominent, the activation of a chronic sinusitis may explain the symptoms. On the other hand, if this is an intestinal infection, and the patient has been abroad, the possibility of chronic bacillary or amoebic dysentery might be considered. It would be advisable in any case to have the chest radiographed and to send a specimen of faeces to the public health laboratory for bacteriological examination, preferably during an attack. If the condition is a recurrent febrile catarrh a course of mixed stock or autogenous vaccine in the "off season" may be of some prophylactic value.

Acrocyanosis

Q.—*What are the latest views on the treatment of acrocyanosis? In spite of wearing warm stockings and gloves a female patient of mine, aged 36, is getting worse. Is there any useful treatment short of lumbar sympathectomy? Are peripheral vasodilators, such as "priscol," worth trying?*

A.—As the question suggests, lumbar sympathectomy is usually a completely successful treatment for acrocyanosis, though it is, of course, justifiable only in the most severe cases. The benefit which one would theoretically expect from peripheral vasodilators is unfortunately not always by any means obtained in practice. Nevertheless, these drugs are worth a trial, and their effectiveness should certainly be investigated in any individual case before surgical operation is undertaken. Priscol, nicotinamide, and hexamethonium should all be given a trial, the dosage being cautiously increased to the limit of tolerance. Unfortunately, it usually happens that the dose which is effective in improving the condition of the legs produces other circulatory symptoms which make the drug useless in practice. At all events, the margin between the effective dose for acrocyanosis and the dose which produces a troublesome fall in blood pressure is a small one; individual response is decidedly variable, so that careful adjustment of the dose for each patient is the only method.

Marbled Skin

Q.—*Can anything be done to mask a very noticeable "marbled skin" in a girl aged 12? The condition is most pronounced on her chest and legs, and the appearance causes her unhappiness.*

A.—Marbled skin, or livedo reticularis, is a normal phenomenon, the blue areas representing parts of the skin where the capillary circulation is sluggish. Accentuation of the pattern is often due to cold and may often be improved if the subject is kept warm. Some accentuated cases appear to be due to an anatomical abnormality in the distribution of skin arterioles, and in such a case treatment is not likely to be effective.

Formerly, livedo reticularis was held to be sometimes an indication of tuberculosis, syphilis, rheumatism, hypothyroidism, and chronic debilitating illnesses. It is doubtful whether these views are widely held nowadays, but they are

worth bearing in mind in the severe case. Improvement of the general health and adequate exercise may be sufficient to convert a disfiguring case of livedo into one well within normal limits where the appearance will no longer trouble the patient.

Bilateral Renal Tuberculosis

Q.—*A woman of 45, who had a nephrectomy for renal tuberculosis six years ago, has still occasional haematuria with dysuria and frequency of micturition. Tubercle bacilli have now been isolated from catheter specimens of urine. (1) Should a full urological examination in hospital be advised to establish the exact site and extent of the lesion, or (2) should streptomycin or P.A.S. (para-aminosalicylic acid) be given without more ado—if so, in what dosage?*

A.—Diagnosis should always precede treatment, and the site and extent of the lesion can be diagnosed only by full urological investigation. If there is a detectable renal lesion on pyelography it is unlikely that streptomycin and P.A.S. will do more than retard its progress, but under their cover a partial nephrectomy might be possible if the lesion is localized.

If no lesion can be demonstrated on the pyelogram it is possible that the urine can be made tubercle negative by a course of treatment; the usual dose is 0.5 g. of streptomycin twice daily up to at least 50 g. and about 2 to 3 g. of P.A.S. three to five times a day. The general regime for any tuberculous patient should be followed.

Emetine and Scorpion Stings

Q.—*One of my dispensary attendants claims that emetine hydrochloride, 1 gr. (65 mg.) intramuscularly, will relieve the pain of a scorpion sting at once, if given within three hours of stinging. Is there any foundation for this treatment?*

A.—The idea that emetine might relieve the pain of a scorpion sting probably arose from the older statement by Simpson that local application of a paste of ipecacuanha was effective. There is little evidence that either is of much value. Injection into the wound of a local analgesic is usually very effective, and serious cases should be given the appropriate antivenin.

NOTES AND COMMENTS

Vitamins during Lactation.—Dr. MAVIS GUNTER (London) writes: Might I make a small addition to your expert's answer about vitamins during lactation ("Any Questions?" January 26, p. 229)? The answer given may leave the impression that cod-liver-oil tablets given to mothers during lactation are of little use. The mother needs to take extra vitamin D not because she is likely to be depleted of that vitamin by its loss in milk, for, as your expert says, that is very little; in lactation, however, she is giving out much calcium, and she will be in negative calcium balance unless she herself has enough vitamin D to enable her to absorb sufficient calcium for her increased need.

OUR EXPERT writes: The vitamin D added to our margarine ration is probably adequate to prevent a negative calcium balance even in lactation, but the use of cod-liver-oil tablets would seem to be amply justified as an additional safeguard.

Speedy Hypnotic.—In the answer to this question ("Any Questions?" January 12, p. 118) the name sodium propylallylbarbiturate was wrongly used for quinalbarbitone (sodium propylmethylcarbonyl allylbarbiturate).

MEDICAL SECURITY IN SWEDEN

BY

DAG KNUTSON, M.D.

President of the Swedish Medical Association; President of the World Medical Association

In many countries there seem to exist, even among doctors, some not very well founded notions on the actual organization of medical service under the present scheme of social security in my country. Time and again colleagues have indicated that they believe in the existence of a far-reaching socialization of Swedish medicine, depriving doctors of professional freedom and intruding upon the relationship between them and their patients.

Many may be the reasons for this. In Sweden as well as in the other Nordic countries social security has reached an advanced standard. We are all inclined to assume that such a state of things must mean a more or less all-embracing regimentation. Again, rumours of radical plans, leading up to the transformation of the profession into a group of full-time employed Civil Servants, may have spread, and these plans could easily be mistaken for an actual system already working. It would be difficult to know to what extent the plans have been made effective—that is, to tell where Sweden now stands.

Such difficulties exist also in relation to the general population of the country. Reforms, incessant planning of new ones, and voluminous investigations, poured forth by numerous State committees and loaded with proposals and Parliamentary decisions for immediate or future use, form a somewhat confused entirety, the description of which runs the risk of becoming out of date the moment it is being published.

Already because of this it is difficult to give a clear picture of to-day's medical services in Sweden, and the complicated aspects which every advanced system of social welfare offers make it impossible to cover the whole field in a short article. It would, though, perhaps be of interest to emphasize a few important features.

Salary and Free Enterprise

In spite of plans, reforms, and decisions it may be said that actual medical services in Sweden still rest on and have grown out of old traditions. There is accordingly still considerable freedom allowed to the doctor, and a third party has as yet hardly entered his consulting-room, harming the relationship between himself and his patient. If there are comparatively few doctors who work purely as private practitioners—15–20% perhaps of the profession—far fewer still could be labelled as full-time employed Civil Servants. One of the peculiarities of the Swedish order of

things, and perhaps the most outstanding one, is this mixture of service and free enterprise.

The general practitioner, found almost only in densely populated centres, shares his time between his practice and some job which gives him a salary and often a pension. As a rule the bulk of his income comes from his practice. The man in salaried service is generally entitled to conduct a private practice, and he often derives a substantial part of his revenue from what he does in independent enterprise. No doctor, of course, can be told what to do with his spare time, and the few full-time employed ones, who are supposed not to advertise a practice, can receive patients in their private office after hours if they want to—and naturally also their due reward.

It should be understood that by service is meant communal as well as State service. District and hospital doctors in towns as well as doctors in the provincial hospitals under provincial governments form one group, and the so-called provincial doctors or doctors in rural districts another. The latter exemplify the State-employed ones. It should also be made clear that only those doctors who are on the staff of a hospital are allowed to work there, unless the hospital is a private one. But there are only half a dozen private hospitals in Sweden, and they are to be found in the two largest cities only. Practitioners therefore cannot as a rule take care of their patients when they send them into hospital. On the other hand, they can use the resources of the hospitals or of polyclinics for technical diagnostic work such as complicated laboratory tests or radiography. They are beginning now to create private laboratories of a capacity equal to those of the hospitals—a promising development.

Fee for Service

The fundamental principle underlying private practice in Sweden is the fee-for-service system. The patient pays his doctor. Exceptions from this rule are few and limited to some polyclinics belonging to university hospitals and hospitals in the three biggest cities. Out-patient departments of other hospitals have developed out of the head doctor's private practice, formerly generally carried on outside the hospitals in his private consulting-rooms, nowadays mostly within the walls thereof, and have retained the old character of private practice in so far as fees are concerned. Even the district doctor in rural districts, who combines the work of a health officer in his district with general practice, is entitled to a fee, paid to him by his patient at the moment of consultation.

This is valid for all patients, whether insured or not. The authorities dislike the system—of course—and plans have come forth aiming at a radical change. For the time being consigned to oblivion because of financial difficulties, these

plans would probably have been realized if State finances had permitted the introduction of compulsory health insurance covering the whole population as well as the creation of a new costly group of Civil Servants—the doctors. Neither has been possible so far, though Parliament has adopted compulsory insurance in principle, and there are those who in this connexion have remembered that no evil is utterly without good aspects.

Voluntary Insurance

But, though doctors in private practice receive their fees from the patients, they are not always free to decide the size of their remuneration. To explain how this matter stands I must touch upon the question of insurance. Health insurance is voluntary in Sweden—it covers some 60 to 65% of the population. Everybody in reasonably good health between 15 and 50 years of age can become a member of his local insurance group. Children under 15 are automatically covered if the breadwinner is insured. It is recognized, and to some extent supported by, the State, but chiefly financed by contributions from the insured themselves, from employers, and from the community. The bulk of the money comes from the first group. Local insurance groups are scattered all over the country and are responsible only for members belonging to their districts.

Under the law, benefits must be of two kinds: for maternity and for sickness. The latter again is twofold; it grants reimbursement for medical and hospital care on the one hand and on the other a daily financial allowance. Of interest for this brief survey is chiefly the reimbursement for medical care.

Reimbursement of Patient

The insurance scheme has a schedule of fees containing every possible service that a doctor can perform. The rates have been set without consultation with the profession and have during the last years become very much out of date. When the doctor completes a case he fills in a form, marking what he has done, and generally also what he has been paid. This form goes with the patient to the insurance office, where every item is looked up in the schedule. Sums shown are added, and the patient gets two-thirds of the total if the doctor has charged just that much or more. If he has charged less, the patient receives two-thirds of what he has paid to the doctor.

Now, the peculiar thing is that most doctors are under no obligation to adjust their fees to correspond with the schedule which the insurance scheme has compiled as a standard. The medical profession has always stoutly refused to consider the insurance rates as anything but a basis for reimbursement, flatly denying that the schedule has anything to do with doctors' fees. The insurance, which at the start did not intend to tie the doctors down to its schedule, has now and then tried to put new ideas forward. But entirely free practitioners constitute an insurmountable obstacle. Hence the official fondness for the thought of doctors as Civil Servants.

Apart from its dislike for ties in general and everything which would promote socialization of the doctor, the profession rejects the structure of the system for reimbursement on principle. The adopted schedule undervalues the work of the doctor, unless it is of a technical nature. If applied to doctors' fees, it might serve fairly well for medical specialties, where costs for swiftly performed minor operations could be added. A surgeon examining a number of small cases in a short time could become a rich man—if it were not for the taxes—whereas a psychiatrist would quickly reach starvation. The profession finds unworthy of its traditions the method of scraping together little things of secondary value in order to arrive at a decent pay for the really important and significant work. The Swedish Medical Association has in fact proposed an altogether different system, aiming at regarding the doctor's perform-

ance as a whole, grading it economically according to completeness and expenditure of time.

The above-mentioned independence of the insurance tariffs exists, it is true, for most doctors in private practice, but there are two exceptions of some importance from this rule. The head doctors of hospitals under provincial governments, being the only specialists available in rural districts, did some years ago accept a tariff for their fees in private practice, and this, though not identical with the insurance scheme's reimbursement schedule, is based on it. As specialists they are entitled to add certain sums, but they are nevertheless tied to the present system for calculating the value of a doctor's work. A most unfortunate thing indeed, and not very necessary, as the authorities themselves pointed out that these doctors (anyway, as a rule) had voluntarily adjusted their fees to suit the reimbursement schedule very well. But even these doctors have a small, absolutely free sector: if a patient wants to come at a special time after surgery hours, the doctor can charge what he thinks is reasonable.

Rural Doctors

The district doctors in the rural parts form the other exception. As an institution they have existed for about 200 years. The regulation of their fees therefore is not really a result of the introduction of an insurance scheme. From the very beginning the district doctors had a salary and a pension: the country population was then too poor to pay fees that would support their doctor. Later on modern ideas transformed this kind of doctor into a health officer with manifold tasks, but he remained all the time, and still is, a general practitioner.

His fees, regulated by the Government and set at a very low level, were linked up with the insurance rates when these appeared, but the level of the fees is still rather lower. From the beginning of the 'twenties it has been altogether out of date, and poverty is no longer a general feature of the rural population. A revision has become urgent, and partly because of this the plans for the new system of appraising the doctor's work were made by the Swedish Medical Association. In principle this system has been adopted by the authorities for the group in question, which is satisfactory. But traditions will prove too strong, and a level common to all doctors connected with the insurance rates will not be reached. The rural district doctor will continue to work for smaller fees than others. But—he will have his fee. His patient will pay him, and through no third party.

A third exception to the rule of independence of insurance rates should perhaps be mentioned, although it lies in a different direction. Medical care of the indigents—fortunately very few in to-day's Sweden—is paid for by the community, and on a fee-for-service basis. But the community pays according to the rates which the insurance scheme has set down as a basis for refund. Indigents are generally referred to polyclinics or district doctors, and the latter are thereby in this connexion tied to officially recognized fees.

This system of separating the theoretical fees of the insurance scheme from the real ones of most practising doctors may seem bewildering. One would suspect that the third party—the patient—would suffer financially through discrepancies between refund and payment. But that has not been so—at least up to the last few years. Investigations made a few years ago by State officials not in the least favourable to the medical profession showed that the insured population received about 85% of what it should have had as reimbursement if all doctors had been obliged to follow the insurance scheme's schedule. In view of the fact that the insurance scheme covers only non-specialist medical care, this shows that the general practitioners, in preparing their bills, have had the insurance rates—that is, the interest of their patients—very much in mind.

To-day such an investigation would probably not give the same result. The rates have not changed appreciably, but

prices have sky-rocketed as a result of the inflation as well as enormously increased wages all through the community. Doctors cannot charge, for instance, ten shillings for a first visit, when the patient costs him about eight; which goes to show that the rates, as has been stated above, must be changed.

On the whole this system has worked well. Above all, it has served one of its main purposes: it has saved the profession, so far, from being socialized. Under the law of compulsory insurance nothing is said about doctor's fees, but unless general ideas change very much the enacting of this law would place the doctors in the risk-zone. Preference has, though, all the time been given to the thought of salaried Civil Servants.

Objections to Capitation Fee

The Swedish authorities do not seem to cherish the idea of a capitation fee. That system of payment does not exist in Sweden, and the profession would under no circumstances accept it—after having studied its effects in Denmark and Germany. Apart from that, the Swedish doctors raise theoretical and, as they think, valid objections to any system which means that the patient does not pay anything to the doctor and *at the moment* when the service is given. The result would inevitably be that the work of the doctor is not appreciated. He loses his patient's confidence, being looked upon more as a servant of the insurance scheme than as a personal friend and helper. The doctor's restrained attitude about the need for medicines and other forms of treatment, or to the need for a prolonged rest-cure, is misinterpreted and becomes to the patient a sign of undue care for the economy of the insurance scheme. The relationship between the doctor and his patient would thus be affected in an unfortunate way—a thing of primary importance.

Furthermore, whatever of freedom and a fair deal may be promised to the doctors, on accepting the capitation fee the profession would enter upon a hazardous venture. The total costs of insurance will for ever be prohibitive and for ever surprisingly much higher than calculations show. In times of stress the cake will be cut in very thin slices. This can now profitably be studied in Germany, where the situation of the doctors is critical—or worse. (In fairness it should be stated, though, that an enormous surplus of doctors complicates the situation in Western Germany. But, having entered upon the system when only one part of the population was covered by insurance, they now find themselves in a situation where the other part no longer exists. Unsound principles, adopted when practical repercussions were unimportant, revenge themselves, and neither the profession nor the population derives any benefits therefrom.)

Moreover, the character of the doctor's work would change, as has been seen in Denmark. Burdensome controls would have to be introduced and patients would come with trifles. Both circumstances would combine to rob the doctor of time for more important work within his own field. Restrictions on the doctor's choice of medicines and other methods of treatment would also be likely. Lists of permitted pharmaceutical preparations might appear. (In connexion with plans for free medicines put out in Sweden such lists became very much of interest.)

In any system involving so-called free medical care the costs have to be carried some other way, and the patient loses every feeling of economic responsibility for his use of the benefits he receives. This makes the task of the doctor even more difficult than it already is. The stress on his personal integrity as well as his willingness to work un-
limitedly for a limited remuneration would become serious. He would probably often find it difficult to perform his tasks in a way which would satisfy his own professional conscience.

Hospital Services

As for hospital services, general wards should be considered as different from private rooms. In general wards, where assistant doctors in salaried full-time employment are responsible for the work under the head doctor, health

insurance pays all the costs of the insured patient. They are calculated as a daily item, covering everything, and are low—about 2-5s. a day. The real costs, though, are eight to ten times higher, and the taxpayer makes up the difference. Everybody can, if medical prerequisites are fulfilled, claim a bed in a general ward regardless of his financial status, and nobody pays anything for medical services given there. The insurance generally reimburses the patient for transport costs to the hospital.

In private rooms patients pay to the hospital more or less what the real costs are, sometimes also a fee to the head doctor. An advisory schedule made up by the Royal Medical Board is at their disposal, but the doctor in charge of the patient is never allowed to demand a fee. Often the estimated income from the private ward is converted into a fixed sum paid annually to the doctor by the hospital: in this case patients do not pay him. The health insurance scheme contributes a daily sum for a member, corresponding to the costs in the general ward.

Conclusion

Space does not allow me to give a report on other forms of medical security in my country. They are numerous and of a kind which is met in most so-called advanced countries. Some of them have the character of public service; doctors taking part in them are often paid in proportion to time spent on the task. Others again are based on the insurance principle. The general tendency is to reject the voluntary in favour of compulsion and to extend public services at the expense of the insurance principle—and the taxpayer. As valuable features of a psychological nature seem to be embodied in both of these principles, which have, among other things, proved their educational merits, the medical profession regards the development with some apprehensions.

I have had to limit myself to some fundamental facts about medical services in my country. I must repeat, though, that very little is static in the modern community. Tomorrow may well reject what to-day accepts as sensible. This is especially true of social security, where responsibilities are rapidly taken from the individual and placed with the community, leaving the former with the rights and the latter with the more or less insoluble problem of how to meet individual needs within the framework of, necessarily unyielding administrative schemes.

EXPENSIVE CHECK

The Government check to eliminate inflation of doctors' lists is estimated to cost £500,000 (*Civil Appropriation Accounts, 1950-1*).

CHARGES ON PRESCRIPTIONS

VIEWS OF G.M.S. COMMITTEE

The following statement has been issued by the General Medical Services Committee:

The Committee has considered the Government's proposal to levy certain charges on prescriptions and is disturbed that it will inevitably introduce a financial barrier between doctors and those who need their services.

Bearing in mind the Conference resolution:

113. *Resolved:* That this Conference places on record its opinion that under no circumstances whatever shall a doctor be required to be an "agent" to collect a Government charge on prescriptions,

the Committee instructs its representatives to press the Government to take such steps during the passage of legislation as will alleviate hardship to certain sections of the population and will ensure that the doctor is not required to play any part in the actual collection of the money.

The Committee reserves its final recommendation to the profession until the arrangements are available in their ultimate form.

HEALTH SERVICE CHARGES

PROVISIONAL DECISION BY G.M.S. COMMITTEE

A special meeting of the General Medical Services Committee was held on February 7, under the chairmanship of Dr. S. WAND, primarily to discuss the Government's proposal to levy certain charges on prescriptions. It was preceded by a meeting of the Rural Practitioners Subcommittee, at which the position of the dispensing doctor was discussed. At both meetings the resolution of the Annual Conference of Local Medical Committees in 1949 (when the suggestion of a charge on prescriptions was first made by the late Government) was reaffirmed:

That this Conference places on record its opinion that under no circumstances whatever shall a doctor be required to be an "agent" to collect a Government charge on prescriptions.

The certainty that the levy would introduce a financial barrier between doctors and those who needed their services also figured largely in the discussion.

Dr. A. BEAUCHAMP opposed the levy on the ground of principle. He believed that it was wrong of a Government to impose a tax on people while they were ill and on the necessities of their illness. If it was true that the country could not afford a comprehensive National Health Service, and that as a social scheme it was financially a failure, the fact should be plainly stated and the whole structure of the Service looked at again with a view to making it a service which the country could afford. The insurance principle, in which premiums covered risks, might have consideration in such a review.

Dr. HOWIE WOOD said that Dr. Beauchamp's point of view would appeal to a number of people in the profession, but they had to be realists and recognize that what was required to be done must be done quickly, without administrative delay and temporary chaos such as Dr. Beauchamp's suggestion would entail. He had heard no criticism in his area concerning the imposition of this charge, although it was agreed that there must be strict provisions to ensure that needy and deserving patients were not penalized. All of them would also agree with the view that the dispensing doctor should not be required to collect the charge. The matter might be met by the purchase of a shilling stamp, to be attached to the prescription form.

Pharmacists' View

The DEPUTY SECRETARY (Dr. Stevenson) said that the National Pharmaceutical Union was calling an emergency conference of pharmacists to consider the situation. The Central N.H.S. Committee had expressed the view that the proposal could work, but only at the expense of considerable hardship on sections of the population. They further said that the proposals should not be resisted to the extent of refusing to operate the scheme, but that they should be subject to special arrangements to meet the rural area problem, that the regulations should include provisions requiring the levy to be paid at the time the prescription was presented for dispensing, that the standard levy should be one shilling for each form, with no exception for prescriptions the N.H.S. value of which was less than one shilling, and that the chemist should be protected effectively against multiple prescribing on a single form and similar abuses. The operation of the levy scheme would necessitate additional pharmaceutical service remuneration.

Sole Criterion

Dr. BRUCE CARDEW said he was bound to put forward the view of his own organization, which had always opposed charges on the Health Service, not on the ground of great hardship but on two fundamental principles: (1) that it should be a comprehensive service in which need was the sole criterion, and (2) that in a public service there should be no requirement to pay twice for the same thing. Those

who paid a water rate did not expect to have to pay in addition so much a gallon. Once the shilling on the prescription had been conceded there would be no ground of principle on which increased charges could be contested. He also pointed out that it would be necessary for dispensing doctors to give a receipt for each shilling—a small matter—singly but, multiplied, likely to be a burden.

Dr. TALBOT ROGERS said that if these charges were imposed, while the profession should do its best to work them, it should ask that the position be reviewed after a convenient time.

After further discussion, in which it was stated that a deputation, on which rural practitioners would be specially represented, would wait upon the Ministry later in the day, the Committee passed a further resolution, which, after reiterating the Conference resolution already quoted, went on:

The Committee instructs its representatives to press the Government to take such steps during the passage of legislation as will alleviate hardship to certain sections of the population and will ensure that the doctor is not required to play any part in the actual collection of the money.

The Committee reserves its final recommendation to the profession until the arrangements are available in their ultimate form.

The deputation was then constituted, consisting of the Chairman of the Committee, Dr. Talbot Rogers (Vice-Chairman), Dr. J. C. Arthur, and Dr. W. Woolley, together with Dr. C. F. R. Killick, the chairman, and other members of the Rural Practitioners Subcommittee.

Dr. WAND said that the deputation would report back to the Committee, and if necessary another special meeting would be called to look at the arrangements before a final decision was made.

The Adjudication

The Chairman outlined the arrangements so far as they had proceeded for the adjudication, and the Committee agreed upon a selection of witnesses representing different areas and types of practice. He said it was hoped that the hearing would begin during March, and frequent meetings were taking place with advisers and counsel.

The first fully constituted meeting of the Working Party would be held on February 26.

Inflation

A letter was read from the Ministry of Health with a redrafted E.C.L. concerning efforts to eliminate inflation. Practically all the points which the Committee had urged had been met by the Ministry. These included an extension of the time from three months to six months, during which a practitioner may provide information concerning the whereabouts of persons whom the executive council had been unable to trace; in the case of untraced persons who turned up after they had been removed from a doctor's list, back credits would be paid to the doctor. The suggestion that executive councils should make use of the electoral rolls, and of information in possession of housing authorities had been accepted. Means would be taken, in communications to the persons concerned, to emphasize the importance of the inquiry and the need for a reply by return.

The Chairman and those associated with him in this piece of work were heartily congratulated on the success of their endeavours.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Southwark, Stoke Newington.

Non-County Borough Councils.—Crewe.

Urban District Councils.—Droylsden, Houghton-le-Spring, Huyton-with-Roby.

SHORT-SERVICE COMMISSIONS

TAXATION OF SUPERANNUATION CONTRIBUTIONS

The Minister of Health has made several "directions" approving various kinds of employment outside the National Health Service, so that doctors leaving the N.H.S. and entering such approved employment for short periods may remain subject to the N.H.S. Superannuation Regulations, Section 19 (2) of the National Health Service (Amendment) Act.

Officers with short-service commissions in the armed Forces can take advantage of this. They have their superannuation contributions deducted from the terminal gratuity and not from current pay. In certain circumstances this could penalize the medical officer. If his commission ended early in the fiscal year the pay for that fiscal year might be insufficient when assessed to allow relief on the full superannuation contributions—i.e., for the whole period of the short-service commission. The gratuity is tax free.

The B.M.A. learns that officers for whom contributions have been paid by the Service department concerned may, on termination of their commission, claim a revision of their earlier years' income-tax liability so as to give them the full allowance to which they would have been entitled had they paid their superannuation contributions from their current Service remuneration.

NEWS IN THE LOCAL PRESS

[FROM A SPECIAL CORRESPONDENT]

The following notes from a lay journalist in the provinces may give some useful tips to Honorary Secretaries and Public Relations Officers of Branches and Divisions.

Many medical groups and societies may not realize that they can build up membership, prestige, and finances without spending a penny. In Great Britain are 1,300 local weekly newspapers and 120 provincial morning and evening newspapers. All are anxious to print in their editorial columns any bona-fide news a group or society can send them.

Weeklies particularly will willingly reserve space regularly if a group can find someone to fill it. Even the morning and evening papers will squeeze an inch from their precious space. A group should therefore appoint a member as press secretary to write a regular piece for the local weekly and keep the press apprised of forthcoming events and developments.

Brevity is the soul of good journalism, especially in these days of paper scarcity, and the press secretary's motto must be "Little but often." Reports should be terse and simple. No blurbs and self-praise are wanted—only news about events, plans, meetings, and personalities. Up to a point the news editor will print items which advertise forthcoming meetings, etc., but these should properly go in the paid-advertisement columns.

The best length to work to in a weekly contribution is about 180–200 words. Better still, ascertain what space there is to spare by ringing up or calling on the news editor. At the same time he could be asked to provide a label side-head—say, "Health News."

The press secretary should see that the news editor has his address and phone number—if possible his business phone number, too, in case he may be wanted to answer an urgent query.

Start Early

Reports should be sent in well before press day, preferably on the Monday or Tuesday. This is the best way of ensuring that a report is printed intact, most weeklies being short of copy at the beginning of the week. If the copy goes in the day before press day it is likely to be blue-

pencilled severely. In the case of an evening paper, copy sent in before noon stands a good chance of getting adequate space, at least in the early editions; for morning papers, send in the copy between 6 and 7 p.m.

Write clearly or type one side of the paper; give ample space between lines, and leave wide margins. Don't pin sheets together; clip them. Carbon copies are permissible, but it is a good idea to write copies separately if one newspaper is likely to give more space than the others.

On the principle that names (of local residents) sell newspapers, editors of local papers like plenty of names in reports, if not dragged in unnecessarily. Their spelling should be accurate, and the initials of Christian names correct, for nothing so infuriates a reader as seeing his name wrongly given.

When special news "breaks," such as the visit of a notability, the news editor should be contacted beforehand if possible. This will give him time to cover the story adequately and assign a photographer if necessary.

A "literary" style should be avoided. Reports should be fair and objective, and comments few and far between. But humour without sarcasm is always welcomed.

Heard at Headquarters

A Matter of Precedence

The solemnities at Windsor sent one curious inquirer back to the old records containing particularized accounts of pre-Victorian royal funerals. One odd thing about them was the place assigned to the medical household in the royal procession. At George III's funeral in 1820, for example, there came first the "backstairs pages," followed by the two apothecaries and six surgeons of the late King and the two apothecaries and ten surgeons of the new King. Then at a little distance, following the grooms, came the higher members of the medical hierarchy, the serjeant surgeons and the physicians-in-ordinary. George IV and William IV were followed in like manner, the apothecaries and surgeons walking with the curate. One departure was made at the funeral of the ill-fated Princess Charlotte, daughter of George IV, and her infant; for in this instance, following the backstairs pages and immediately preceding the apothecaries, came the solicitor. Further along in the same procession were the medical men who had been in attendance at Her Royal Highness's confinement—John Sims, the consulting accoucheur, Matthew Baillie, the consulting physician, and Sir John Croft, who delivered the Princess, and who, a few weeks later, poor man, in his chagrin and mental distress, ended his life.

State Occasions

The late Lord Dawson of Penn, who was himself a conspicuous figure at the funerals of two monarchs—Edward VII and George V—was not only the King's physician, but a master on all questions of procedure and precedence on such occasions. As a privy councillor and an upholder of tradition these matters really interested him. Sometimes he intervened with suggestions for an alteration of arrangements. A few weeks before the death of George V, Dawson had attended at Windsor the funeral of the King's sister, the Princess Victoria. His biographer tells us that he had requested beforehand that the draft of the funeral service should be submitted to him to secure its brevity in view of the feeble state of the King. This was not done, however, and far too long a service was the result. Dawson watched the King in St. George's Chapel, weighed down in body and mind, and compelled to stand for overlong, and within little more than a month the King himself had followed his sister to the tomb. It was at the funeral of George V that Neville Chamberlain, catching sight of Dawson, was reminded to send him a line of appreciation of the beautiful words of the last bulletin: "The King's life is moving peacefully to its close."

Correspondence

Health Service Charges

SIR,—At a special meeting held on February 10 the physical aspects of the 1s. payment in a rural practice were the main theme. The aspects of dignity, fairness, exemptions, and finance were not forgotten. But it was felt that our allowing one and a half minutes to give change or certify an exempted person to each of half of the day's cases added up to the doctor being away from the clinical side of his practice, without any deputy, for 10 days in each year. The state of affairs proposed would be so ridiculous that the following was passed:

The East Norfolk Division B.M.A. is adamant in its decision not to add the duties of a tax collector to its obligations as general practitioners.

Most of us are aware of the tremendous waste of money and manpower in the administration of the Health Service from assistant deputy office messengers to motor-cars and chauffeurs, and it seems more equitable to concentrate on them than on the "sick" patient.—I am, etc.,

A. H. GREGSON,
Hon. Secretary, East Norfolk Division.

SIR,—Most practitioners must welcome the Government's attempt to introduce some degree of economy in the cost of prescriptions. But is a shilling on each prescription the best method to achieve this objective? There will be many objections raised. Would it not be a better practice that the patient should pay the chemist the actual price of all items costing less than 2s. 6d.? This would not only effect a considerable reduction in the number of prescriptions going through the mill of pricing bureaux—thus reducing administrative costs—but would not penalize those patients who require more expensive and often more important therapeutics. The diabetic, for instance, under the shilling-an-item scheme may often find his prescriptions costing him 5s. or 6s., when many would consider that he should receive his essential requirements without cost. Whereas the small charge of 1s. may be insufficient to deter the habitual "bottle of medicine" addict, a charge of about 2s. 6d. would be a reasonable deterrent—at any rate he would better appreciate the value of his medicine.

I believe that this alternative suggestion would effect an even greater saving in the cost of the pharmaceutical service and at the same time be an easier and fairer method of distributing the "surcharge."—I am, etc.,

Newton Abbot, Devon.

ANGUS EVERARD.

SIR,—In the dilemma to save on the N.H.S.'s drug bill but not to cause hardship it seems to me the following arrangement would be a solution. All patients who have a certificate of unfitness to work—that means who have to live on National Insurance money—should be exempted from the shilling charge. The same should apply, naturally, to old-age pensioners.

In both cases the doctor has the necessary information to mark the prescription form in a way which can be agreed upon. This would have the desired effect of discouraging the habitual visitors to surgeries but exempting the neediest.—I am, etc.,

Birmingham.

T. LASZLO.

Paying for the Health Service

SIR,—Mr. H. A. Marquand (*Journal*, February 2, p. 272) is right in stressing the necessity to dispel the belief that the Health Service is paid for by the insurance fund, in order to induce patients to be economical in their use of it. But who is responsible for this fallacy? Should not that man (I need not remind you of his name) who was Minister of Health when the Service started have ensured that the public were properly informed?

I rejoice that at long last another economic measure is to be introduced, the 1s. charge per prescription, for this will make for contented doctors by reducing frivolous calls on their time, despite the fact that "that man" considers it unnecessary and undesirable; does he consider contented doctors to be unnecessary and undesirable also?—I am, etc.,

London, S.E.27.

F. H. HUNNARD.

Branch and Division Meetings to be Held

DUDLEY DIVISION.—At Bell Hotel, Market Street, Stourbridge, Thursday, February 21, 7.45 for 8.15 p.m., dinner. Principal guest, Dr. S. Wand, Chairman, Representative Body, B.M.A.

ENFIELD AND POTTERS BAR DIVISION.—At Eastern Gas Board Offices, Palace Mansions, Sydney Road, Enfield, Wednesday, February 20, 8.45 p.m., film meeting. Medical films: (a) "Oxygen Therapy"; (b) "Foxgloves in Medicine."

GREENWICH AND DEPTFORD DIVISION.—At Miller Hospital, Greenwich High Road, London, S.E., Wednesday, February 20, 8.30 p.m., B.M.A. Lecture by Dr. Keith Simpson: "Foul Play."

NORTH MIDDLESEX DIVISION.—At North Middlesex Hospital, Silver Street, Edmonton, N., Tuesday, February 19, 8.45 p.m., ordinary meeting; 9.20 p.m., short papers by Dr. Kathleen Dalton, Dr. M. P. K. Menon, and Dr. E. T. Bannister.

NORTH OF ENGLAND BRANCH.—Thursday, February 21, 7.15 p.m., scientific meeting, clinical demonstration by Mr. John Swinney; address by Professor J. Chassar Moir: "Some Queens of England and their Confinements."

OLDHAM DIVISION.—At Oldham Hotel, Rhodes Bank, Monday, February 18, 9 p.m., Dr. Benjamin Portnoy: "Diet in Diseases of the Skin."

ROCHESTER, CHATHAM, AND GILLINGHAM DIVISION.—At Kent County Ophthalmic and Aural Hospital, Maidstone, Thursday, February 21, 8 p.m., clinical meeting. All medical practitioners in the area of the Division are invited.

WEST DENBIGH AND FLINT DIVISION.—At Royal Alexandra Hospital, Rhyl, Thursday, February 21, 8.30 p.m., exhibition of sound films from B.M.A. film library: (a) "Control of Infection in Surgical Dressings"; (b) "Thrombosis and Embolism."

WESTMINSTER AND HOLBORN DIVISION.—(1) At the Refectory, Westminster Hospital, London, S.W., Thursday, February 21, 6.30 for 7 p.m., dinner meeting. (2) At Meyerstein Lecture Theatre, Westminster Medical School, Horseferry Road, S.W., 8.30 p.m., B.M.A. Lecture by Dr. J. A. Gorsky: "Medico-Legal Investigation of Murder." Medical and legal guests of members are invited.

Infantile Scurvy and Sub-Scurvy

THE INFLUENCE OF VITAMIN C DEFICIENCY

In the case of a baby which is pale and fretful ; not feeding or thriving well ; showing low resistance to infection and slow healing in the event of wounds, it is often advisable to examine the possibility of a lack of Vitamin C as the basic cause.

If the child is *BREAST FED* it is probable that the mother is not eating a sufficiency of fresh fruit and vegetables or is in poor health with anorexia, anaemia and fatigue. She may indeed be suffering from sub-scurvy herself, yet wishes to continue breast feeding.

If the child is *BOTTLE FED*, the mother may have omitted to give some fresh fruit juice, possibly because the baby may be sick on such additions. It is well to remember also that cow's milk has less than one third of the Vitamin C content of human milk and that this is further reduced by pasteurisation.

In order to remedy Vitamin C deficiency and so restore the devitalised health which may otherwise end in symptoms of scurvy with its painful muscular haemorrhages and rapid heart failure, the use of Delrosa Rose Hip Syrup is confidently recommended. Delrosa is the richest natural source of Vitamin C, is very palatable and quickly absorbed. It provides all the Vitamin C necessary for positive health, the development of new tissue (such as red blood cells, new bone and teeth cells) and for cementing the walls of blood vessels and other tissues. Because of its high Vitamin C content (57 mgms. per fluid oz.), Delrosa plays a large part in preventing bacterial infections and in establishing immunity.

Delrosa is obtainable from all chemists.

6 oz. bottle 2/-

Double size 3/6d.

Every fluid ounce of Delrosa provides 57 mgms. Vitamin C, 100 calories, 65% sugars and an appreciable quantity of Glucose for energy.

Just what the Doctor Ordered!

A doctor's life means
hard wear for clothes—
hours of car-driving result
in a shiny seat and shoulders.
A suit tailored in Sportex,
Scotland's hardest wearing cloth,
is the answer—ask your tailor.

Sportex

SCOTLAND'S HARDEST WEARING CLOTH

Are you 'at Home' to Germs

Surely the provision of a means of protection against airborne bacteria is of prime importance in your consulting and waiting rooms?

It is here that you come into close contact with your patients, and they with each other. Here where the risk of cross-infection is so great.

A Hanovia Bactericidal Unit generating bactericidal ultra-violet rays, either suspended or wall mounted, is normally adequate for a medium-sized room. These units, made for A.C. mains, are quiet, automatic and inexpensive in operation.

Write for our leaflet "Applications of Air Sanitation."

The facts about Glucose

Glucose, a term used to include a substance resulting from the partial hydrolysis of starch, is in practice a general description rather than a precise one. It is applied to medical preparations which contain additives that may not always be wanted and to commercial products of varying degrees of refinement. To identify Glucose in its purest form, and only in this form, the term Dextrose is used.

Dextrose, as found in the blood and tissues, is the sugar into which the body converts all carbohydrates. Requiring neither digestion nor chemical alteration, Dextrose is used by the body as a source of immediate energy.

The Dextrose (pure medicinal Glucose) produced by the Pharmaceutical Division of Corn Products Company Limited is prepared in two convenient forms:—

Dextrosol Powdered Glucose

This contains no additives of any kind. It can be taken in large quantities without causing nausea, and should be prescribed in all cases where a patient needs a source of heat and energy with the least demand on the digestion. Packed in 1 lb. cartons.

Dextrosol Karo Glucose Syrup

for Infants and Children

An appetising blend of pure Glucose and selected carbohydrates, carefully balanced to provide the ideal sugar addition to the milk diet of artificially-fed infants. Of special value in cases of nutritional disorder. Spread on rusks, bread, etc., it offers an excellent supplementary source of energy for growing children. Packed in 1 lb. tins. A Karo Baby Book is available for the guidance of mothers.

Professional samples of both Dextrosol products will be gladly provided. For further information, doctors are invited to write to the Dextrosol Information Bureau, Wellington House, 125/130 Strand, London, W.C.2.

The "Cestra" Mask

For SURGEONS and NURSES

BACTERIOLOGICALLY TESTED AND
SPECIALLY DESIGNED FOR THE
PREVENTION OF DROPLET INFECTION

After many bacteriological experiments, this mask was designed to arrest all droplets from the mouth and nose, and so prevent contamination during operations. The "Cestra" mask consists of 4 layers of Fine Dental Gauze. It fastens securely under the chin, has an air gap at the sides, is comfortable to wear for long periods and may be easily sterilized.

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held; £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not Registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

Applications are invited for the position of **ANAESTHETIC REGISTRAR (Non-resident)** to reside within reasonable distance of the hospital. The appointment is subject to review after one year. A local charge will be made for any residential amenities provided. Applications (in duplicate), stating date of birth, full details of qualifications and experience, present appointment, grade and salary, together with two copies of two recent testimonials, should reach C. E. Nicol, Secretary, North-East Metropolitan Regional Hospital Board, 11a, Portland Place, London, W.1, by Saturday, March 1, 1952. (8165)

GRIMSBY AND DISTRICT GENERAL HOSPITAL

Sheffield Regional Hospital Board
Applications are invited from registered medical practitioners for the resident whole-time post of **REGISTRAR (Anaesthetics)**

to the above hospital, which is recognized for training for the D.A. The appointment is for one year in the first instance and may be renewed for a further year. Applications, giving age, nationality, qualifications, present and previous appointments (with dates), together with names and addresses of three referees, should be sent to the Secretary, Sheffield Regional Hospital Board, Fulwood House, Old Fulwood Road, Sheffield, 10, to arrive not later than March 4, 1952. (7978)

NEWCASTLE REGIONAL HOSPITAL BOARD

Regional Chest Surgery Centre (160 beds), Shotley Bridge Hospital and associated sanatoria

WHOLE-TIME ANAESTHETIST (Senior Registrar)
Locum tenens appointment tenable up to August 31, 1952. It is possible that a longer term senior registrar post will be available after August 31, but this will be subject to open competition again. The great bulk of the work in the main centre, i.e., excluding the sanatoria, is concerned with non-tuberculous conditions (mediastinal, oesophageal, cardiovascular as well as pulmonary). Candidates must possess a D.A., have had considerable experience with anaesthesia, and preferably have had a sound preliminary general medical and/or physiological training. Appointee must be prepared to take an active part in clinical and physiological investigations, preoperative and postoperative management of patients in addition to undertaking the customary duties of an anaesthetist. The allocation of these duties may have to be varied from time to time according to clinical requirements by arrangement with the Senior Anaesthetist, but usually the work will be divided between the Centre and the Sanatoria. Appointment subject to National Health Service (Superannuation) Regulations, 1950. Applications, giving details of qualifications, and experience, together with copies of one to three testimonials, and/or the names and addresses of one to three referees, should be sent to the Senior Administrative Medical Officer, Newcastle Regional Hospital Board, Blythwood South, Osborne Road, Newcastle, 2, within fourteen days. Candidates are entitled to visit the hospitals by arrangement with the Senior Surgeon, Regional Chest Surgery Centre, Shotley Bridge Hosp. (7979)

GERMAN HOSPITAL, Dalston, E.8

Applications are invited for the post of **SENIOR HOUSE OFFICER (Resident Anaesthetist)**. The successful candidate will also be required to act as Casualty Officer. The appointment is for a period of one year in the first instance. Salary £670 per annum, less £130 per annum for residential amenities. Applications, with copies of three testimonials, should reach the Group Secretary, Hospital Management Committee, Administrative Offices, Hackney Hospital, London, E.9, within six days of the appearance of this advertisement, quoting the reference GH/1. (8094)

WOOLWICH GROUP HOSPITAL MANAGEMENT COMMITTEE**SENIOR HOUSE OFFICER (Anaesthetics)**

The appointment is to the Woolwich Group of hospitals and is tenable for one year, resident for six months at St. Nicholas Hospital, Plumstead, and for six months at Memorial Hospital, Woolwich. These hospitals are recognized for the D.A. Salary £670 per annum, less £150 per annum for board and lodging. Applications, together with copies of two recent testimonials, to be sent to the Sec., Memorial Hospital, Woolwich, S.E.18. (8126)

BIRMINGHAM, 18, DUDLEY ROAD HOSPITAL

(900 beds)
Birmingham (Dudley Road) Group of Hospitals
RESIDENT SENIOR HOUSE OFFICER
(Anaesthetics)

Applications are invited for the above post, which becomes vacant on April 1, 1952. The person appointed will be based at Dudley Road Hospital, but duties within the Group may occur. This hospital is recognized for training for the Diploma in Anaesthetics. Applications, stating age, nationality, qualifications and experience, and accompanied by copies of three recent testimonials, should be sent within seven days to the Secretary, Hospital Management Committee, Dudley Road Hospital, Birmingham, 18. (8127)

CHESTER AND DISTRICT HOSPITAL MANAGEMENT COMMITTEE

Applications are invited for the post of

RESIDENT HOUSE OFFICER (Anaesthetist)

The post is recognized for the D.A. The successful applicant will be required to carry out duties in conjunction with the present Resident Anaesthetist at Chester Royal Infirmary and Chester City Hospital and will require to reside at the Chester Royal Infirmary. Salary £670 per annum, less a deduction of £150 per annum in respect of board and lodging, etc. Applications, giving details of age, experience and qualifications, together with copies of two recent testimonials, should be sent as soon as possible to L. V. Pollard, Secretary, 5, King's Buildings, Chester. (8166)

Anaesthetics—contd.**BARNET GENERAL HOSPITAL, Barnet, Herts**
RESIDENT SENIOR HOUSE OFFICER
(Anaesthetics)

Required for one year from February 25. Post recognized for D.A. examination. Applications, stating age, qualifications, nationality, experience and names of two referees, to be sent to the Medical Director. (7766)

KEIGHLEY AND DISTRICT VICTORIA

HOSPITAL, Keighley (146 beds)

BINGLEY HOSPITAL, Bingley (68 beds)

Yorkshire, West Riding

(Full Consultant Staffs)

Applications are invited for the appointment of

SENIOR HOUSE OFFICER in Anaesthetics

(Either sex)

for duty at the above hospitals for the acute sick, resident at Keighley Victoria Hospital. Twelve months' appointment. Vacant now. Salary £670 per annum. National Health Service terms and conditions. Applications, stating age, qualifications, experience and nationality, together with copies of recent testimonials, to be forwarded as soon as possible to the Secretary, Bingley, Keighley, Skipton and Settle Hospital Management Committee, St. John's Hospital, Keighley. (7325)

LEICESTER GENERAL HOSPITAL (445 beds)

Applications are invited for the post of

CHEST PHYSICIAN

(Senior Hospital Medical Officer scale) to undertake hospital and clinic duties in No. 2 Area (County Armagh and part of County Down). Applicants must have had wide experience in the diagnosis and treatment of tuberculosis. Possession of a higher medical qualification is desirable. The person appointed will work under the direction of the Consultant to the Area. Forms of application and conditions of appointment may be obtained from the Secretary, Northern Ireland Tuberculosis Authority, 27, Adelaide Street, Belfast, with whom completed applications should be lodged not later than February 22, 1952. (8080)

NORTH GLOUCESTERSHIRE CLINICAL AREA
South-Western Regional Hospital Board

Applications are invited from registered medical practitioners for the appointment of

Whole-time ASSISTANT CHEST PHYSICIAN

on the Senior Hospital Medical Officer scale to the North Gloucestershire Clinical area. Applicants should possess high medical qualifications, and previous experience in diseases of the chest is essential. The successful candidate will be required for duty mainly at Salterley Grange Sanatorium, near Cheltenham (78 beds), where he will be required to reside. A furnished flat suitable for a married man is provided. Duties may include visits to other hospitals and sanatoria in the area, as may be determined by the Regional Board from time to time. The successful candidate, who will work under the supervision of the Senior Consultant Chest Physician in the area, will be given some chest clinic duties partly in the Birmingham Region. The successful candidate will also be required to collaborate with the medical officers of health of the local health authorities concerned in connection with the tuberculosis service. Opportunities will be given for experience in mass radiography. Fifteen copies of applications, stating date of birth, qualifications, and experience, together with fifteen copies of two testimonials, and the names and addresses of two referees, should be sent to the Secretary of the Regional Hospital Board, 5, Cotham Lawn Road, Bristol 6, not later than March 7, 1952. (8219)

WEST CORNWALL CLINICAL AREA
South-Western Regional Hospital Board

Applications are invited by the Regional Hospital Board and Cornwall County Council from registered medical practitioners for the appointment of

ASSISTANT CHEST PHYSICIAN

in the West Cornwall Clinical Area, which comprises the districts of Truro, Bodmin, Newquay, St. Austell, Falmouth, Redruth and Penzance. The appointment will be on a whole-time basis in the Senior Hospital Medical Officer grade, subject to possible adjustment in respect of local authority work. Applicants should possess high medical qualifications, and previous experience in diseases of the chest is essential. The successful applicant will be required to work under the general direction of the Senior Consultant Chest Physician, and the duties will be mainly concerned with the conduct of chest clinics in the area. Arrangements will be made for some in-patient work. He will also be required to collaborate with the County Medical Officer of Health in connexion with the tuberculosis services. Twelve copies of applications, stating date of birth, qualifications and experience, together with twelve copies of two testimonials, and the names and addresses of two referees, should be sent to the Secretary of the Regional Hospital Board, 5, Cotham Lawn Road, Bristol 6, not later than March 7, 1952. (8252)

Applications to Secretary, Westwood Hospital, Beverley, Yorks. (7691)

CHESTER, COUNTY MENTAL HOSPITAL

Applications are invited for the following vacant post:

PSYCHIATRIC SENIOR HOUSE OFFICER

Salary £670 per annum. Accommodation available for a single man, or a house for a married man, for which a charge will be made. All forms of modern treatment available including insulin unit. There are psychiatric out-patient clinics at three general hospitals, occupational therapy units and voluntary treatment wards. Facilities given to study for higher qualifications. Apply Medical Superintendent. (7778)

GLASGOW, STOBHILL HOSPITAL

Western Regional Hospital Board, Scotland

Applications are invited from suitably qualified medical practitioners for the following appointment, which will be for one year in the first instance:

SENIOR HOUSE OFFICER in Psychiatry

Applications, stating age, qualifications and experience and present appointment, and giving the names of three referees, should be submitted not later than February 28, 1952, to the Secretary, Board of Management for Glasgow Northern Hospitals, 13, Woodside Place, Glasgow, C.3. The above appointment will be subject to the N.H.S. (Scotland) (Superannuation) Regulations. (8138)

OXFORD, WARNEFORD AND PARK HOSPITALS

Oxford Regional Hospital Board

Applications are invited for an appointment as

SENIOR HOUSE OFFICER

at the above hospitals. The Warneford Hospital (140 beds) is in process of development as an acute psychiatric unit, with special emphasis on postgraduate training and facilities for research. It is closely associated with the adjacent Park Hospital (a neurosis centre of 30 beds, with daily out-patient clinics) at which the successful candidate will have ample opportunities for working. Experience can thus be gained in all branches of psychiatry, including child psychiatry. The appointment, now vacant, is specially suitable for a young graduate beginning the study of psychiatry with a view to specialist training and higher qualification, and every facility will be granted for these purposes, including opportunities for attendance at other appropriate hospitals in Oxford. The clinical work and postgraduate training in the hospitals is conducted on the system of two medical firms each headed by a consultant, and the House Officer will have experience with both. Accommodation is available for an unmarried candidate, but permission to live out of the hospital, subject to the usual terms of duty, may be granted if married. Salary and conditions of service in accordance with national scales. Applications, together with copies of recent testimonials, should be sent to the Medical Superintendent, Warneford Hospital, Oxford, within fourteen days of the appearance of this advertisement. (8258)

ISLEWORTH, WEST MIDDLESEX HOSPITAL
South-West Middlesex Hospital Management Committee**FULL-TIME RESIDENT HOUSE OFFICER**

(Second or third post), Department of Psychiatry. Previous medical experience essential and psychiatric experience an advantage. Department includes a neurosis centre and observation wards, and conducts extensive out-patient service. Applications (endorsed "House Officer, Psychiatry, West Middlesex Hospital"), stating age, nationality, qualifications and experience, with copies of up to three recent testimonials, to Secretary, West Middlesex Hospital, Isleworth, by Feb. 26. (8185)

IMPORTANT: All intending applicants should read the revised NOTICE at the top of page 19

IMPORTANT: All intending applicants should read the revised NOTICE at the top of page 19

PUBLIC HEALTH

(See Important Notice page 21)

BIRMINGHAM, CITY OF Public Health Department

Applications are invited for the appointment of **ASSISTANT ADMINISTRATIVE MEDICAL OFFICER**

in the Maternity and Child Welfare Department. The work in this department includes duties in connection with children of all ages in the care of the Children's Committee. Applicants should have had experience in work with mothers and children, including a six months' resident post in a maternity hospital and in a children's hospital. The D.P.H. or the D.C.H. and any administrative experience will be considered an additional qualification. The salary scale is £1,050 by £50 to £1,250, the commencing salary within the scale depending on the medical officer's experience. The appointment is subject to the provisions of the Local Government Superannuation Act, 1937, and the successful candidate will be required to pass a medical examination. The appointment will be subject to one month's notice on either side. Applications, endorsed "Assistant Administrative Medical Officer for Maternity and Child Welfare," giving full details of training and experience, together with copies of three recent testimonials, should be submitted on a form obtainable from the Medical Officer of Health, Council House, Birmingham, 3, and returned to him on or before March 3, 1952. (8205)

GLAMORGAN EDUCATION AUTHORITY Rhondda Urban District Council Committee for Education

Applications are invited from registered medical practitioners for appointment as

ASSISTANT MEDICAL OFFICER

under the supervision of the District School Medical Officer at a salary of £850 per annum, rising by annual increments of £50 to £1,150 per annum. Preference will be given to candidates holding the D.P.H. or D.C.H., and experience in paediatrics will be an advantage. The successful candidate, if in need of housing accommodation and not already a resident of the Rhondda Urban Area, may be offered the tenancy of a Council house. Forms of application and conditions of appointment may be obtained from the District School Medical Officer, Tydfil House, Pentre, Rhondda, by whom completed applications should be received as soon as possible.—D. J. Jones, Clerk of the Council. (8280)

GLOUCESTERSHIRE COUNTY COUNCIL ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH (Male)

Salary in accordance with the Whitley Council for Health Services, Medical Council, £850 per annum, rising by annual increments of £50 to £1,150 per annum. The commencing salary within this scale will be determined in accordance with the candidate's previous Local Government experience. Applicants must be registered medical practitioners and the possession of a Diploma or Certificate in Public Health will be an advantage. The appointment will be superannuable and the successful applicant will be required to pass a medical examination. Candidates must be able to drive and be in possession of a car, travelling and subsistence allowances will be paid in accordance with the Council's scale. Forms of application, with particulars of duties and conditions of appointment, may be obtained from the County Medical Officer of Health, Berkeley House, Berkeley Street, Gloucester, to whom completed applications should be sent within fourteen days of this advertisement.—Guy H. Davis, Clerk of the County Council, Shire Hall, Gloucester. (7975)

IPSWICH, COUNTY BOROUGH OF ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

Applications are invited from registered medical practitioners for the above post. The possession of the D.P.H. or the D.C.H. is a desirable qualification although not essential. Salary will be £850 by £50 to £1,150 per annum. A commencing salary above the minimum of the grade may be fixed, having due regard to the experience of the applicant. The post is established and superannuable. The officer appointed will be required to provide, maintain and use a car in the course of the duties, for which an allowance will be paid. Application forms and conditions of appointment may be obtained from the Medical Officer of Health, Elm Street, Ipswich.—J. C. Nelson, Town Clerk, Town Hall, Ipswich. (7976)

LINCOLN, COUNTY OF—PARTS OF LINDESEY ASSISTANT COUNTY MEDICAL OFFICER AND DISTRICT MEDICAL OFFICER OF HEALTH for Horncastle Rural, Horncastle Urban and Woodhall Spa Urban Districts

Applications are invited from any duly qualified medical practitioner registered in the *Medical Register* as the holder of a Diploma in Sanitary Science, Public Health or State Medicine, for the above-mentioned combined appointments providing whole-time employment. The combined salary will commence at £1,040 2s. 1d. per annum and will rise by four annual increments of £52 12s. 1d. and two annual increments of £42 3s. 9d. to a maximum of £1,334 17s. 11d. per annum. Travelling allowances according to the County Council's scale will be paid. The appointment of District Medical Officer of Health will be made by the District Councils in accordance with the Local Government Act, 1933, and the Sanitary Officers' (Outside London) Regulations, 1935, as amended by the Sanitary Officers' (Outside London) Regulations, 1951. The appointment will be superannuable. Applications, on forms obtainable from the Clerk of the County Council, County Offices, Lincoln, must be returned not later than ten days after the appearance of this advertisement.—H. Copland, Clerk of the Lindsey County Council, Lincoln. (7846)

SWANSEA, COUNTY BOROUGH OF

Applications are invited from duly qualified medical practitioners for the post of **ASSISTANT MEDICAL OFFICER (Female)**. Applicants must have had postgraduate resident hospital experience and should be under 45 years of age unless already holding a similar superannuable appointment. Salary £850 by £50 to £1,150 per annum. Application forms may be obtained from the Medical Officer of Health, Public Health Department, The Guildhall, Swansea, to whom they should be returned not later than Monday, February 25, 1952. Canvassing, either directly or indirectly, is a disqualification.—T. B. Bowen, Town Clerk, The Guildhall, Swansea. (8206)

TOTTENHAM, BOROUGH OF

Applications are invited for the post of **DEPUTY MEDICAL OFFICER OF HEALTH** from duly registered medical practitioners holding the Diploma of Public Health. The officer appointed will be required to devote 30 per cent of his time to the work of the Area Health Service of the Middlesex County Council. The salary will be £1,298 15s. per annum, rising by five annual increments of £53 15s. and one of £18 15s. to £1,586 5s. per annum. The appointment is subject to the provisions of the Local Government Superannuation Act, 1937, and to the satisfactory passing of a medical examination. Details of the terms of the appointment may be obtained from the Medical Officer of Health, Town Hall, Tottenham N.15. Applications must comply with the above-mentioned conditions and must be received by the undersigned in envelopes endorsed "Deputy Medical Officer of Health," not later than 12 noon on Saturday, March 1, 1952. Canvassing disqualifies.—M. Lindsay Taylor, Town Clerk, Town Hall, Tottenham, N.15. (8145)

WORCESTERSHIRE COUNTY COUNCIL ASSISTANT COUNTY MEDICAL OFFICER with Additional Public Health Duties

Applications are invited from registered medical practitioners (men or women) for the above whole-time post. The duties will chiefly concern school health and child welfare services. The possession of the D.C.H. or the D.P.H. and experience in connexion with infectious diseases will be of advantage. The salary and conditions of service will be in accordance with the recent award of the Industrial Court, i.e., £850 per annum, rising by annual increments of £50 to £1,150. Past experience will be considered in fixing the starting point within the scale. The successful candidate must own and drive a car. The holder of this appointment (now vacant) also acted as occasional Deputy at the Hayley Green Isolation Hospital and to the Medical Officer of Health for the boroughs of Halesowen and Stourbridge, for which additional payment is made. The appointed officer will be considered for all or any of these additional appointments. The post is superannuable, subject to medical examination and determinable by three months' notice. Applications, on forms to be obtained from the County Medical Officer, County Buildings, Worcester, should be returned to him by February 29, 1952.—W. R. Scurfield, Clerk of the County Council (X42). (8272)

Public Health—contd.**WARWICKSHIRE COUNTY COUNCIL**
County Medical Officer of Health's Department
TWO ASSISTANT COUNTY MEDICAL OFFICERS OF HEALTH (Male or female)

Applications are invited from registered medical practitioners for the above permanent appointments. Preference will be given to those holding D.P.H. or D.C.H. and with previous experience. Salary according to experience within the following scale: £850 per annum by annual increments of £50 to a maximum of £1,150 per annum. The posts are superannuable and appointment is subject to the production of a satisfactory medical certificate. The successful candidates will be required to provide and use a motor car in the performance of their duties, for which a mileage allowance is payable. Further particulars (including details of area) and application forms may be obtained from the County Medical Officer of Health, Shire Hall, Warwick. Closing date for applications is March 1, 1952. —L. Edgar Stephens, Clerk of the Council, Shire Hall, Warwick. (7977)

GOVERNMENTAL**PRISON AND BORSTAL SERVICE**

Applications are invited for three posts of **PSYCHIATRIC SOCIAL WORKERS (Women)** at Liverpool, Manchester and London. Salary £420 by £20 to £580 per annum. Starting pay according to age, experience and qualifications. Pensionable under the Health Service Superannuation scheme. Applicants must hold the Mental Health Certificate of either the University of Edinburgh, London, or Manchester, and should preferably be experienced in mental work. Regulations and application forms from Establishment Officer (E84/3/6), Prison Commission, Horseferry House, Dean Ryle Street, London, S.W.1, to be returned by March 1, 1952. (8273)

HER MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom with one or more years' experience after qualification are required for appointment as **MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH**

for General Medical and Health duties. Appointment is available (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale 1952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in Her Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a), including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a), including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e., those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/242/51). (5187)

GOVERNMENT OF INDIA

Required for the Irwin Hospital, New Delhi, under the Colombo Plan for Technical Co-operation in South and South-East Asia, an

ORTHOPAEDIC SURGEON

with postgraduate qualifications and at least ten years' experience in the practice and teaching of orthopaedics, to act as Consultant and to train postgraduate and undergraduate students. The Irwin Hospital is a general hospital of 300 beds with a large surgical section where all types of general surgery, including orthopaedics, are done. Candidates should be between 30 and 55 years. Two-year appointment in first instance with first-class return passage. Salary £3,250 (taxable in this country) with substantial allowances (tax free) and free board and lodging. Write, giving age, full particulars of experience and qualifications, to the Secretary (Division 5A), Ministry of Health, Savile Row, London, W.1. (7730)

UNIVERSITY OF THE WITWATERSRAND
Johannesburg, South Africa

Applications are invited for appointment to three posts of **FULL-TIME LECTURER**

on the permanent staff of the Department of Anatomy. The salary scale attached to the appointment is £550 by £25 to £800 per annum, plus a cost-of-living allowance which amounts to £208 per annum in the case of a married man or a single person with dependants, and £109 per annum in the case of others. The duties involve the teaching of gross anatomy and/or microscopic anatomy and embryology to undergraduate medical, dental and science students. Applicants need not be medically qualified and those with good qualifications and teaching experience in fundamental sciences, such as zoology and comparative anatomy, will also be considered. Duties are to be assumed as soon as possible. Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5, Gordon Square, London, W.C.1. The closing date for the receipt of applications is April 7, 1952. (8274)

UNIVERSITY APPOINTMENTS**BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH**

Notice is hereby given that an election of Junior Fellows to begin work on October 1 next will take place in June, 1952. Junior Fellowships are of the annual value of £600 for three years with, in certain circumstances, superannuation benefits to which the successful candidates will be required to contribute 5 per cent of the annual stipend and to which the Trust will make a contribution of 10 per cent. Candidates must have taken a degree in a faculty of a university in His Majesty's Dominions, Protectorates and Mandated Territories, India, Pakistan, and the Republic of Ireland approved by the Trustees, or a medical diploma registrable in the United Kingdom. Elections to Junior Fellowships are rarely made above the age of 35 years. Applications from candidates must be received not later than April 14, 1952. Candidates must submit evidence that they can be given accommodation in the departments where they propose to work, which must be either in Great Britain or Ireland. Forms of application and all information may be obtained by letter only, addressed to the Secretary, Beit Memorial Fellowships for Medical Research, The Lister Institute, Chelsea Bridge Road, London, S.W.1. For overseas candidates forms of application may be obtained from the Secretary, South African Medical Council, P.O. Box 205, Pretoria, South Africa; The Secretary, Universities Commission, Box 4061, G.P.O., Sydney, Australia; The Department of Health, Wellington, New Zealand; and the Canadian Medical Association, 184, College Street, Toronto, Canada. (4503)

NUFFIELD FOUNDATION MEDICAL FELLOWSHIPS

As part of its programme for the advancement of health the Nuffield Foundation is prepared to award a number of Fellowships to highly qualified medical men and women of the United Kingdom, usually between the ages of 25 and 35, who wish to train further for teaching and research appointments in any branch of medicine. Between equally qualified applicants preference will be given to those who wish to pursue an academic career in child health, social medicine, industrial health, psychiatry, and chronic rheumatism. Applications for awards in 1952 must be received not later than May 1, 1952. The value of the awards will be variable but will not be less than £900 per annum plus travelling expenses. The conditions of these fellowships and the application forms are obtainable from the Secretary, The Nuffield Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1. —L. Farrer-Brown, Secretary of the Nuffield Foundation. (7796)

University Appointments—contd.

GONVILLE AND CAIUS COLLEGE, Cambridge
BERKELEY BYE-FELLOWSHIP
 (Founded in memory of Sir G. H. A. Comyns Berkeley and of his wife, Ethel Rose Berkeley)

The Council of Gonville and Caius College invite applications for a Berkeley Bye-Fellowship for research in either of the following fields: (1) Medicine. (2) Any branch of Natural Science, excluding Medicine. Candidates should be men of not less than twenty-six years of age. The tenure of the Bye-Fellowship is from one to three years and the emolument from £500 to £1,000, according to standing. Full particulars may be obtained from the Registrar, Gonville and Caius College, Cambridge. Applications must be received not later than April 1, 1952. (7851)

INSTITUTE OF UROLOGY

in Association with St. Peter's and St. Paul's Hospitals

PART-TIME BIOCHEMIST

(Medical qualification not essential)

Required to undertake research and laboratory investigation in connexion with urological disease. Graduates of at least two years' standing may apply. Appointment (approximately half-time) might suit applicant engaged in preparing thesis for higher degree. Salary commencing at £450 per annum. Apply, Secretary, St. Paul's Hospital, Institute of Urology, Endell Street, W.C.2, stating age, qualifications and experience, and enclosing copies of two recent testimonials. Closing date February 25, 1952. (7787)

WELSH NATIONAL SCHOOL OF MEDICINE
 (University of Wales)

Applications are invited for the appointment of **FULL-TIME ASSISTANT LECTURER**

in the Department of Obstetrics and Gynaecology for a period of one year in the first instance. Salary within the range £650 by £100 to £950 per annum, with participation in family allowance and superannuation schemes. Further particulars of the appointment may be obtained from the undersigned, by whom applications must be received not later than Saturday, March 8, 1952.—F. Dodsworth, Secretary, 34, Newport Road, Cardiff. (8275)

NOTICES

APPLICANTS ARE ADVISED NOT TO SEND original testimonials when replying to advertisements. Copies will answer the purpose quite as well, and in the event of their being lost or mislaid no inconvenience will ensue.

FACULTY OF ANAESTHETISTS
ROYAL COLLEGE OF SURGEONS OF
ENGLAND

Annual General Meeting

Notice is hereby given that the Annual General Meeting of the Faculty will take place at the College in Lincoln's Inn Fields, London, W.C.2, on Wednesday, March 19, 1952, at 4 p.m. Notices of motion must reach the Secretary by not later than Saturday, March 8. An Agenda Paper will be available three days before the date of the meeting and will be issued to any Fellow or Member who applies for it. All Fellows and Members of the Faculty are eligible to attend the Annual General Meeting.—W. F. Davis, Secretary. (8106)

MINISTRY OF LABOUR AND NATIONAL
SERVICE

Medical Boards and Disablement Advisory Committees

From time to time vacancies occur in the panels of medical practitioners who are prepared to serve, required, as members of National Service Medical Boards. Such Boards meet at intervals according to the requirements of the area, and payment on a sessional basis. A general practitioner wishing to be considered for any vacancy which might arise in the panel of the Medical Board nearest to the district in which he resides should make his wish known to the appropriate Local Medical Committee or to the Secretary, Ministry of Labour and National Service, Cumberland Terrace, London, N.W.1. Occasional vacancies also occur in the membership of that Department's disablement Advisory Committees and their panels. A general practitioner wishing to be considered for such appointment should similarly apply to the Local Medical Committee or the Secretary, Ministry of Labour and National Service, 32, St. James's Square, S.W.1. A one year full-time course, leading to a Diploma in Microbiology, will start in October, 1952. The course will cover the biology and biochemistry of the bacteria and yeasts and fungi. Candidates who already hold the degree of B.Sc. with honours may read for the degree of M.Sc. The number of places is limited and applications for admission, with details of previous training, should be made to the undersigned, from whom further information may be obtained, by May 31, 1952.—A. W. Chapman, Registrar. (8162)

TANCRED'S STUDENTSHIPS

Divinity, Medicine, Law

£100 per annum each. For men only

About Whitsuntide next the Governors propose to elect one Student in Physic at Gonville and Caius College, Cambridge, and one Student in Law at Lincoln's Inn. Candidates must have been born in England, Scotland or Wales and be members of the Church of England and unmarried. An examination will be held at Caius College on Wednesday, April 16, 1952, for Physic candidates who must be within the ages of 17 and 22 years. The Law candidates, who must be within the ages of 20 and 23 years, must have passed an approved examination of school certificate standard. The last day for sending in petitions for the Physic and Law Studentships is March 11, 1952.

A Divinity Studentship will be awarded later in the year, on the result of the scholarship examinations conducted in December by the Queen's, Christ's, St. John's, Emmanuel and Sidney Sussex Group of Colleges, in the University of Cambridge. A further announcement relating to the Divinity Studentship will appear in this Journal in September.

Apply for further particulars and form of petition, stating kind of Studentship and mentioning this Journal, to the Clerk, R. M. C. Howard, Esq., D.S.O., 28, Lincoln's Inn Fields, London, W.C.2. (7788)

Readers frequently desire to refer to advertisements concerning appliances, preparations, etc., which have appeared in earlier issues of the Journal.

LECTURES

FACULTY OF ANAESTHETISTS. PHARMACOLOGY LECTURES.—A short course of 10 lectures in Pharmacology will be given by Dr. H. C. Stewart and Dr. A. H. Galley. This course will take place at the Royal College of Surgeons from April 21 to 25 and there will be two lectures each day, one at 5 p.m. and the other at 6.15 p.m. The fee for these lectures will be £2 2s. or 5s. per lecture. Applications should be made to the Secretary, Faculty of Anaesthetists, Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2 (HOLborn 3474) (8233)

FACULTY OF ANAESTHETISTS. ROYAL COLLEGE OF SURGEONS.—A course of 40 lectures in Anaesthetics will be given at the College from March 24 to April 4, 1952. Fee £15 15s. A series of Tutorials in Anaesthetics will be held during the same period and will consist of 10 one-hourly sessions commencing 5.30 p.m. Fee £10 10s. For further details, apply to the Secretary, Faculty of Anaesthetists, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (HOLborn 3474). (8234)

UNIVERSITY OF LONDON.—A LECTURE ON "The Pathology and Treatment of Portal Hypertension" will be given by Professor R. Milnes Walker (Bristol) at 5.30 p.m. on February 26, at Westminster Medical School (Meyerstein Lecture Theatre), Horseferry Road, S.W.1. Admission free, without ticket.—James Henderson, Academic Registrar. (8163)

UNIVERSITY OF LONDON.—A LECTURE ON "Antidiuretic Effects of Blood and Urine in relation to Neurohypophyseal Secretion" will be given by Professor H. B. van Dyke (Columbia University) at 5 p.m. on February 25, at University College (Physiology Theatre), Gower Street, W.C.1. Admission free, without ticket.—James Henderson, Academic Registrar. (8164)

SITUATIONS VACANT

North Devon Hospital Management Committee.—**Pathological Laboratory, Bampton Street, Barnstaple.**—Applications are invited for the post of **Technician or Junior Technician** in a new laboratory serving the North Devon District. Considerable experience in haematology is essential. Salary and conditions in accordance with Whitley Council scales. Applications, stating age, qualifications and experience, together with the names of two referees, to the Pathologist at the above address. (8100)

Situations (Vacant)—contd.

New Zealand Health Department.—Applications are invited from suitably qualified physiotherapists to fill the following positions at the Queen Elizabeth Hospital, Rotorua. **Staff Physiotherapist, Cerebral Palsy Unit.** Salary £N.Z.437 a year, rising to £N.Z.575 a year by annual increments of £N.Z.23. Credit will be given in commencing rate for hospital experience since registration. Applicants must be registered physiotherapists. Appointee will normally be required to live out, but temporary accommodation can be offered at the hospital for women only at a cost of £N.Z.126 10s. a year. **Physiotherapists.** In addition to the above, three vacancies exist for Staff Physiotherapists in the Physiotherapy Department. Salaries and conditions of appointment same as for vacancy above. Further particulars, application forms and conditions of employment may be obtained from the High Commissioner for New Zealand, 415, Strand, London, W.C.2 (mentioning this *Journal* and quoting reference No. 16/195/31), with whom completed applications in duplicate should be lodged not later than March 31, 1952. (8146)

**PHARMACISTS,
DIETITIANS, DISPENSERS, NURSES
VACANT**

Dispenser Receptionist required. Two employed, Midlands.—Box 405, B.M.J.

Resident dispenser required country practice, Leicestershire, would suit older person requiring accommodation for self and relatives.—Box 542, B.M.J.

AVAILABLE

Dispensing Assistant (lady), with Apothecaries' Hall Certificate, seven years' hospital experience, free immediately for locum duties.—Box 634, B.M.J.

**RECEPTIONISTS, SECRETARIES,
TYPISTS, ETC.**

AVAILABLE

Experienced Secretary, used medical phraseology, excellent shorthand-typing and references, seeks part or full employment with doctor in West Central London.—Box 616, B.M.J.

Experienced S.R.N., C.M.B. (Part I), trained shorthand typist, seeks post as full-time Secretary-Receptionist at a specialist's practice, aged 27. Able to drive car. Speaks fluent Danish.—Box 514, B.M.J.

Experienced doctor's Secretary, high speeds shorthand typing initiative, accuracy, requires post, full- or part-time. Excellent references. Moderate salary. West End preferred.—Write Box 615, B.M.J.

Lady requires post as Secretary-Receptionist to specialist or doctor. Several years secretary/shorthand-typist, three years medical secretary.—Box 635, B.M.J.

Lady desires post with doctor. Willing to help in household, if necessary.—Box 637, B.M.J.

Lady with long experience desires engagement as Secretary or Receptionist to medical or dental practitioner.—Write Miss Beers, Wold, Northampton.

Lady, well educated, intelligent, administrative and some nursing experience, good driver, typing, but no shorthand, seeks post as Receptionist/Secretary with doctor or dentist in Central London. Very good references.—Box 601, B.M.J.

London Receptionist-Secretary seeks similar post offering married accommodation.—Please telephone Miss Baker, Popesgrove 2778, evenings.

Qualified occupational-therapist, secretary requires work as receptionist/secretary in London.—Box 628, B.M.J.

Nurse, aged 23 years, preliminary State examination, seeks post as Receptionist to doctor or dentist in London area.—J. Runckles, 80, Gurney Court Road, St. Albans, Herts.

Secretary desires post, London area, experienced medical and psychiatric work. Good French, German.—Box 636, B.M.J.

Secretary, hospital and private practice experience, seeks new situation. London only.—Box 607, B.M.J.

S.R.N., experienced, aged 39, knowledge shorthand-typing, pleasant personality, good appearance, seeks position medical receptionist.—Box 629, B.M.J.

Well-educated young lady, thorough knowledge medical terms, especially psychiatry, shorthand/typing, requires post Secretary/Receptionist. London area.—Box 638, B.M.J.

Applicants requiring testimonials, theses, copied or duplicated should communicate with Manton Secretarial Service, Ltd., 98, Victoria Street, S.W.1 (Victoria 0141), who are specialists.

Thoroughly trained Medical Secretarial staff may be engaged through Brook Street Bureau, Ltd., 59, Brook Street, W.1, Gro. 6666, and 2, George Street, Croydon. Phone: 3363.

HOUSES FOR SALE

Harley Street. Modern attractive house would be sold, owner leasing back ground floor for own consulting rooms, vacant possession of remainder, costly marble mantels, mahogany doors, parquet floors, etc., £12,500 for 65 years at only £125 per annum ground rent.—Box 641, B.M.J.

ACCOMMODATION**AVAILABLE**

Norfolk Hall, 25, Norfolk Square, W.2. Quiet, well-appointed accommodation. Car parking facilities, from 4½ guineas. Dinner, bed and breakfast. Resident Proprietor. Tel.: Pad. 8596.

W.2. In medical household. Furnished bed-sitting room, use of kitchen and bath. 3½ guineas.—Box 609, B.M.J.

CONSULTING ROOMS, ETC.**AVAILABLE**

Harley Street. Modern building. Large, light Consulting Room, usual services.—Box 620, B.M.J.

Queen Anne Street. Excellent part-time Consulting Room, central heating, plate on door. Rent £100. Free March 25.—Apply Box 619, B.M.J.

Two quiet consulting-rooms, waiting-room, attend-ance. Also bed-sitting room.—10, York Gate, Regent's Park. WELbeck 4844.

BEJECTAL *with Liver*

REGD TRADE MARK

Injectable B Complex Vitamins, Abbott

Bejectal with Liver is a sterile, parenteral vitamin B complex solution for intramuscular injection. It contains not only the components stated below but also the lesser known members of the B complex as contained in Crude Liver Extract.

Bejectal with Liver is ideally suited for prophylaxis and for the treatment of deficiencies of the vitamin B complex—especially in cases where oral administration is not practical and where synthetic components alone are not fully effective.

COMPOSITION

PER CC.		PER VIAL (10 CC.)
10 mg.	Aneurine Hydrochloride B.P.	100 mg.
0.5 mg.	Riboflavine B.P.	5 mg.
10 mg.	Nicotinamide B.P.	100 mg.
5 mg.	Pantothenic Acid (as calcium pantothenate)	50 mg.
12 mg.	Choline	120 mg.
<i>Liver Injection (Crude), 2 U.S.P. units (injectable) per cc. q.s. to 1 cc.</i>		
<i>Phenol, 0.5 per cent as a preservative.</i>		

ADMINISTRATION

The dose of Bejectal with Liver which must be injected intramuscularly will vary with the severity of the condition treated. One cc. supplies a minimal therapeutic dose. Larger doses should be given in cases of severe vitamin deficiency, but divided doses tend to give maximal efficiency of utilization. Bejectal with Liver is supplied in bottles of 10 cc.

When anxiety
makes life a burden...

To the patient suffering from emotional imbalance, the ordinary problems of everyday life can appear insuperable, and physical symptoms may also develop. The elimination of possible causes — economic, social, or domestic

— is not always practicable; tactful reassurance must often be enhanced by active therapy. In cases of depression associated with anxiety 'Drinamyl' induces a sense of tranquillity and relieves mental and emotional distress.

'DRINAMYL'

is remarkably helpful

Samples and further information are available on request

'DRINAMYL' TABLETS

Available, on prescription only, in bottles of 25 tablets. Each tablet contains 5 mg. dextro-amphetamine sulphate ('Dexadrine') and 32 mg. (gr. $\frac{1}{2}$) amylobarbitone.

MENLEY & JAMES, LIMITED, COLDHARBOUR LANE, LONDON, S.E.5 /

A DAILY MULTIVITAMIN SUPPLEMENT
FOR CHILDREN AND CONVALESCENTS . . .

* Vi-Magna

MULTIVITAMINS

Lederle

Multivitamin formulas are now widely used by physicians for both the prevention and the treatment of nutritional depletion . . . for those about to undergo, or who have undergone, surgical procedures . . . in nutritional deficiencies in the aged . . . in convalescents, especially those recovering from infection . . . and in patients suffering from prolonged serious illness. VI-MAGNA Multivitamins *Lederle* provide a full daily supplement of essential vitamins to offset insufficient content of vitamins in the diet, faddist or inadequate general food intake, impaired intestinal absorption, or poor utilization.

FORMULA

Capsules: Each capsule contains Vitamin A, 5,000 Int. Units; Vitamin D (Calciferol), 500 Int. Units; Thiamine HCl (B₁), 3.0 mg.; Riboflavin (B₂), 2.0 mg.; Niacinamide, 20.0 mg.; Calcium Pantothenate, 1.0 mg.; Pyridoxine HCl (B₆), 0.2 mg.; Ascorbic Acid (C), 75.0 mg. FOLVITE* Folic Acid, 1.0 mg.; with excipients, flavouring and artificial colouring

Packages:

Bottles of 30, 100
and 1,000 Capsules.

(From the Rheumatism Department, West London Hospital)

In a preliminary study of the therapeutic effects of cortisone and other steroid substances in rheumatoid arthritis, certain methods of objective assessment by which relatively small clinical variations can be detected were described (Copeman *et al.*, 1950). The application of these methods to a further series of patients with active rheumatoid arthritis under treatment with cortisone for longer periods is the subject of the present report.

We have been mainly concerned in devising a suitable method of administration which will suppress the disease indefinitely and enable the patients to resume useful and independent lives, free from unpleasant side-effects. Haematological and metabolic changes occurring during routine administration of cortisone were investigated, and such side-effects as did occur in this small series were studied in detail.

Selection of Patients

The patients selected had suffered from active and undoubted rheumatoid arthritis for at least six months, and in most cases much longer, as shown by the clinical signs and a raised erythrocyte sedimentation rate. They were all regarded as "severe cases," since they could not carry out their normal occupation and had already become dependent on others. They described themselves as "crippled," though, since the joint changes as studied radiologically were often minimal, much of their disability was potentially reversible.

*This study was aided by grants from the Medical Research Council, the Empire Rheumatism Council, and the Dan Mason Research Foundation of the West London Hospital Medical School.

Each of the 20 cases was observed for at least three months. Thirteen have been examined in detail by the methods of assessment previously described, with the addition of a finger-ring test (Hart and Clark, 1951), and concurrent metabolic studies. The remaining seven patients, who provided their own cortisone, were placed in the same clinical category, though they were submitted to a less extensive metabolic study. The length of study under continuous administration was as follows:

Months:	3	4	5	6	7	8	9	10	Total
No. of cases	1	3	4	3	6	1	1	1	20

Dosage Schedule

On the assumption that cortisone does not cure rheumatoid arthritis but only suppresses the disease (Hench, 1950), it was decided that as soon as the symptoms had been relieved adequately the dose should be lowered to a level at which this improvement might be maintained for a prolonged period without the appearance of undesirable reactions. Such a scheme has recently been favourably reported on by Boland (1951), who studied a much larger series for a longer period. Our dosage schedule therefore consisted of the following three phases: a period of initial high (suppressive) dosage; a period of gradual reduction of dosage; and a period of minimal (maintenance) dosage.

In most cases cortisone has been given by intramuscular injection during the first two periods (initial suppression and reduction of dosage). When the minimal maintenance level has been found the oral route was used. In this way we were able to compare the relative effectiveness of muscular and oral administration; furthermore, it was much more convenient for out-patients to take the compound by mouth.

Initial Suppressive Dosage

Two initial dosage schemes have been studied: (1) The "classical" method described by Hench, Kendall, Slocumb, and Polley (1949) in their original report—namely, 300 mg. on the first day, 200 mg. on the second, 150 mg. on the third, and subsequently 100 mg. daily; and (2) 100 mg. daily from the first day onwards. Doses of more than 100 mg. were divided into two injections, whereas 100 mg. and below was given once a day.

A daily dose of 100 mg. has been given until the patient has improved enough to lead a comfortable life and to have a reasonable prospect of returning to work. This level of improvement is assessed by the methods already described, which are based on disappearance of pain and tenderness and performance of functional tests (Copeman *et al.*, 1950). If possible, the patients leave the hospital for a day or two to test their functional capacity in their home surroundings.

Ten patients have been treated according to scheme 1 and 10 patients according to scheme 2. It is our impression that the lower dosage is sufficient and gives a smoother response, though there may be no measurable improvement for five to seven days.

"Boost" Dosage.—In our recent cases we have given a higher dose—200 mg. a day for 7 to 10 days—at the "comfortable" stage, which usually develops 14 to 21 days after treatment has begun, in order to obtain further improvement. Increasing experience with the "classical" initial dosage scheme has led us to the conclusion that, despite dramatic loss of pain and tenderness, patients who had often been "crippled" for months might be unable to take full advantage of the improvement owing to their prolonged relative immobility, and that they tended to develop pains due to muscular strain. By giving the "boost" dosage for a short time after the patients had been rehabilitated and had been free from pain for two weeks or more we frequently obtained a further gratifying degree of improvement.

Period of Gradual Reduction of Dosage

At a stage when the disease process seems to be satisfactorily under control the daily dose is reduced by 12.5 mg. (0.5 ml.) at a time. During this stage we find that careful methods of assessment are most important, as it is only in this way that the lowest maintenance dose can be found. The patient, knowing the dose is being reduced and fearful of relapse, will tend to exaggerate minor changes. Originally the dose was reduced every two or three days, but this proved to be too rapid, and dose reduction every five to seven days seems to be more satisfactory. The daily dose is raised by 12.5 mg. or more on changing over to oral administration, since, as other workers (Boland and Headley, 1951) have found, oral dose requirements are slightly larger. Eventually the oral dose is lowered in the same way as described for diminution of the intramuscular dose.

Maintenance Dosage

Because most cases of rheumatoid arthritis will require prolonged treatment with cortisone, as low a maintenance dose as possible must be found. Although this may need to be increased temporarily during periods of physical and mental stress, it will remain effective in most cases for prolonged periods without relapses occurring, and may even in some cases be further diminished as time goes on.

When the oral maintenance dose has been established the patient is discharged from hospital, encouraged to return to his normal duties, and asked to attend once a week for clinical and haematological assessment.

Oral Dosage.—The relative effectiveness of intramuscular and oral maintenance doses is subject to individual variations. In some cases the difference between the two is not more than 25 mg. a day. In at least one case (Case 7) the response seemed to be actually better when the drug was taken by mouth. In Case 6 it was impracticable to administer the drug intramuscularly as the patient was

having a large dose of insulin at the same time. We have used "cortone" tablets in a few cases, but most of the oral administration has been in the form of the aqueous crystalline suspension produced for intramuscular injection, which is satisfactory except for its obnoxiously bitter taste, to which most patients become accustomed. We recommend that the dose should be measured accurately with a syringe into a spoon; in view of the tendency of the crystals to adhere to the sides of glass great care should be taken that none of the dose is wasted.

Clinical Assessment

The methods of assessment which we have previously described have provided a satisfactory means of controlling the dosage of cortisone. We now rely on them to a much greater extent than on metabolic or pathological investigations, including even the sedimentation rate. The methods as described are rather laborious for day-to-day clinical use, so that the full joint chart and set of functional tests are now completed only from time to time, six or seven representative joints and tests being chosen for day-to-day assessment.

Of the tests described, joint tenderness continues to correlate accurately with the clinical state. We are less impressed with the tests involving the study of the range of movement of individual joints—unless, as in the knee-joint, the range can be accurately measured between two fixed points—because the increase in range of movement is either too obvious to need measuring, or, if it is slight, measurements are not accurate enough to eliminate the error due to subjective bias on the part of the assessor.

We find the grip test particularly useful if the fingers, hands, or wrist-joints are involved. Similarly, the ring-size test is an accurate and objective measurement of the swelling in the interphalangeal joints.

Where stiffness is a prominent feature, tests involving speed of movement—for example, the speed with which the arms can be "flailed" or lifted vertically above the head in a fixed period of time, usually 15 seconds—are especially useful. Where the lower limbs are predominantly involved the rheumatoid "flop" disappears early in treatment and its study is of little use in assessing progress in the later stages; but the ability to stand on a chair without holding on, to kneel, and to lie on the ground and get up without help, or—in bedridden patients—the speed at which they can flex and extend their knee-joints, are all satisfactory tests.

In general it is important to choose the tests individually for each patient according to his particular disabilities. No single quota of tests can possibly be satisfactory if indiscriminately used.

Results

Of the 20 patients treated, improvement was graded as good in 12 cases (fully employed in normal work and able to undertake normal recreation and normal housework); fair in 5 cases (fully employed in light work—limited recreation and all but heaviest housework); and definite but poor in 3 cases (unemployable—limited physical activity—light housework).

Table I shows that cortisone treatment has enabled 17 of the patients chosen for this study to leave hospital and resume their previous work or, in the case of the women, carry out normal housework. In three patients the results were disappointing. In one (Case 4) we were unable to find a maintenance dose low enough to avoid adverse effects. In the other two (Cases 16 and 19) permanent joint damage was too severe for the patients to become independent of help.

In Case 1 cortisone appeared to induce a complete clinical remission which has lasted so far for eight months. In spite of this the patient has had a persistently raised sedimentation rate, suggesting that the condition is latent and not cured.

The maintenance dose necessary to keep a patient comfortable varies considerably from case to case, but the

requirements of any single individual fall within a small range—for example, 25 mg. We have not seen the type of case reported by Boland (1951), in which maintenance requirements fluctuated wildly and inexplicably. No case has so far become refractory on prolonged administration. We have not been able to determine any factors which will enable us to predict in advance whether a patient will need a high

or a low maintenance dose. As our cases were chosen from those showing the disease in a highly active condition, though the permanent deformity was not extensive, we are unable to correlate dosage with the duration of the disease, but our results do not suggest that there is a significant relationship between dosage and the degree of activity of the disease as judged on a clinical and haematological basis.

TABLE I.—Results

Case No.	Age and Description	Clinical Assessment and Duration of Disease	Initial Dose High or Low	Maintenance Dosage (mg.)		Result
				I.M.	Oral	
1	Married woman aged 50. Housework	Rheumatoid arthritis 2 years. Unable to run house or carry anything for 11 months. Walked 100 yards with difficulty. Wakened every night by pain	High	37.5	37.5	After 3 weeks' administration was able to return home and lead a normal life, including housework. Cortisone gradually reduced, and stopped after 6 months. No signs of relapse 7 months after suspending administration
2	Unmarried woman aged 55. Company secretary	R.A. 4 years. Unable to work for 2½ years. Walked ¼-mile slowly. Continually wakened by pain. Large synovial swellings on dorsum of both wrists and knees	High, and "boost" dose of 200 mg./day for 4 days on 98th day and 5 days on 134th day	75	70	Able to resume full-time secretarial work 6½ months after starting administration. Successfully ran her own flat for 4 months. This patient was found dead in her flat on 8/8/51, having been at work the previous day. Necropsy (Dr. Keith Simpson) revealed a massive intracerebral haemorrhage
3	Married woman aged 34. Housework and 3 children	R.A. 16 months. Light cooking; nothing else. Wakened ½-hourly by pain for 2½ years	High, and "boost" dose of 200 mg./day for 13 days on day 101	75	87.5–100	Able to lead a completely normal life, including housework, care of children, shopping, while under administration. Knees relapsed rapidly whenever dosage was cut to below her maintenance dose; the rest of her joints retained their improvement
4	Married woman aged 38. Housework and child	R.A. 20 months. Unable to dress herself or do housework for over a year. Could shuffle only 300 yards. Had not slept well for 18 months. Could not get into a bath	High, and "boost" dose of 200 mg./day for 6 days on day 40 and 7 days on day 84	75	100	Able to run her home and look after her child and do light gardening. Administration suspended because of side-effects. Rapid relapse
5	Married woman aged 46. Housework and child (Figs. 1 and 4)	R.A. 5 years. Rapid deterioration in last 3 months. Able to do only very light housework. Continually wakened by pain	Low	62.5	80	Can lead a normal life as a housewife
6	Army officer aged 31. Married	R.A. 2½ years. Partly bedridden; with great difficulty could walk 30 yards. Unable to dress or climb stairs. Wakened for 6 months nightly by pain	Low	75–100	75–100	Starting training as a telephone operator. Can travel independently
7	Married woman aged 34. Housework	R.A. 9 years. Permanent flexion deformity in one knee. Could walk only 100 yards. Unable to dress herself or get into a bath. Unable to run her home	High, and "boost" dose of 200 mg./day for 10 days at day 14	100	100	Can carry out all domestic duties except those involving kneeling; runs her home by herself, which she has not been able to do for years. Able to go out visiting and to theatres
8	Married woman aged 40. Housework	R.A. 2 years. Could walk only ½ mile very slowly. Unable to do her own hair for 5 months. Could not get into bath or climb stairs	Low, and "boost" dose of 200 mg./day for 10 days at day 21	100	100	Symptomless on high dose, but gets side-effects. Comfortable but not symptomless on lower dose
9	Married man aged 44. Superintendent water inspector (Fig. 2)	R.A. 12 years. Rapid deterioration, in last 2 years. Unable to work	High	50	62.5	Has returned to full employment. Work involves much travelling, walking, stair-climbing. Completely free from pain and tenderness
10	Unmarried woman aged 32. Clerk	R.A. 5½ years. Unable to work for the past 18 months. Could walk only ½ mile slowly and with a limp. Could not get into a bath	Low, and "boost" dose of 200 mg./day for 15 days on day 14	25		Apart from her wrist-joints, which are permanently deranged, she can lead a normal life. Can do only light clerical and housework because of her wrists
11	Married woman aged 38. Housework and child	R.A. 26 months. See Case 4. Entire relapse within month of stopping treatment. On objective tests was significantly worse than on previous occasion	Low	100	100	Can do housework and look after child, light gardening, and shopping. Still discomfort on overexertion
12	Married man aged 34. Civil servant	R.A. 9 months. Could only dress himself slowly and incompletely. Had not slept well for 9 months. Unable to climb stairs or get into a bath	Low, and "boost" dose of 200 mg./day for 13 days on day 16	62.5	75	Returned to work. No pain or analgesics. Able to dress completely at normal speed. Sleeping well
13	Married woman aged 37. 3 children. Housework and 1 child to look after	R.A. 4½ years. Cannot dress herself. Help required to do stairs. Wakened by pain during the night	High	50	50	Able to do housework and take part in family life—dancing a little and light gardening
14	Married woman aged 59. Household duties	R.A. 8 months. Febrile. Swelling and pain in interphalangeals, wrist, knees, and feet. Confined to bed with pain	Low	75	50	Free from pain and able to live a slightly restricted but normal life
15	Business man aged 46	R.A. 6 years. Had to give up attending his business. Could barely walk with difficulty; in constant pain	High	75	50	Walks slowly with some pain, but can get to his work
16	Business man aged 50	R.A. 10 years. Could get about only with difficulty; in constant pain	Low	50	50	Can walk without a stick. Some permanent deformity in hands. Can work only part-time
17	Unmarried woman aged 41. School-teacher	R.A. 3 years. Interfering intermittently with her work as a teacher. Faced with possibility of permanent inability to continue working	"	50	50	Able to return to work
18	Married woman aged 27. Housework and 2 children	R.A. 9 years. Gradual deterioration in last 3 years. Barely able to look after herself and children. Unable to do housework. Walked with a stick	"	62.5	75	Able to lead a normal life
19	Unmarried woman aged 35. Independent means	R.A. 9 years. Ankylosis of right knee. Chair-bound	High	50	50	Able to walk without sticks. Less rest pain
20	Business man aged 66	R.A. 1 year. Practically bedridden and able to attend to his business only intermittently	"	100	100	Able to return to work after 2 months

FIG. 1.—Case 5. Low initial dosage. Relapse at 9th week, when oral dose was reduced too quickly, and slight relapse at 19th week after changing to oral therapy in insufficient dosage.

Side-effects

Our series has been notable so far for the absence of serious side-effects, and in only Case 4 have they been severe enough to cause us to stop administration of the drug. Table II summarizes all the side-effects observed. In nearly every case they were slight, and might have been ignored but for the alarming reports which have been published by other observers.

Injection Abscesses.—Cortisone acetate is prepared in a microcrystalline suspension which forms a depot at the site of the injection. The injections are painless if they are placed deeply in the intramuscular tissue. An abscess may start from injection into the superficial fat, from an intramuscular haematoma, or from imperfect skin sterilization. The onset is insidious, with mild local pain but no constitutional disturbance. This failure of constitutional response can be most misleading, and in our early cases caused us to delay incision until a large amount of pus had accumulated, with considerable necrosis of the gluteal muscles. If recognized in time we have found that most of these abscesses can be satisfactorily dealt with by aspiration of the pus through a wide-bore needle and local replacement by the appropriate antibiotic.

Rounding of the Face.—This complication occurred in five cases. In two the patient was having a "boost" dose of 200 mg. a day when it appeared. In these cases it con-

dose only

FIG. 2.—Case 9. —Previous improvement with A.C.T.H. and relapsed to 50%. High initial dosage and adequate suppression of arthritis at oral maintenance dosage of 62.5 mg. a day.

sisted of a mild degree of "moon face"; there were no supraclavicular pads, no dorsal hump, no striae, and no acne, but one of the patients subsequently developed an excess of fair fine hair on her cheeks and lips. The third case (Case 6) developed a rounding of the face in association with a significant degree of water retention. Case 4 developed a "moon face," supraclavicular pads, and a small dorsal hump, but no other manifestations of Cushing's syndrome. As it was impossible to control this patient's arthritis on a lower dose and as she objected on cosmetic grounds, treatment was suspended. The nature of the "moon face" in Cushing's syndrome is not properly understood, nor is its significance in cortisone and A.C.T.H. therapy. From our brief experience with these substances it would appear that a "moon face" may occur in the absence of any other manifestation of Cushing's syndrome and is therefore merely of aesthetic concern to the patient.

Carbohydrate Tolerance.—No patient developed persistent glycosuria during treatment, but ketone bodies were occasionally found, in some cases without glycosuria. Case 6, however, had been rendered diabetic by a previous course of high-dosage A.C.T.H. therapy. (This case is to be reported in detail later.) When cortisone treatment was started he was insulin-sensitive and the diabetes was well controlled with 12 units (P.Z.I. and soluble) given once a day; but cortisone rendered him insulin-insensitive, for a time, though his urine is now sugar-free on 104 units of insulin a day. It was considered justifiable to continue treatment in spite of the insulin resistance, as he was responding so well and would have become totally crippled had cortisone treatment been stopped.

Fluid Retention Causing Oedema.—Fluid retention causing temporary oedema has occurred in four cases. In Cases 7 and 8 it developed while the patient was on the "boost" dose of 200 mg. a day and soon disappeared when the dose was reduced. In Cases 6 and 20 it was controlled by moderate salt restriction in the diet.

Psychic Effects.—Possibly because our patients were chosen, among other things, for their mental stability and intelligence, we have not encountered any serious psychic effects. Some of them complained temporarily of mild exhaustion and apathy. Two complained of a feeling of tension and quick temper while on the high dosage; one complained for a short period of a feeling of unreality. There has been an absence of pathological euphoria, and in no case was insomnia a prominent symptom. Some of the patients complained of transient morning headaches, which may have been associated with mild psychological symptoms already described.

Spontaneous Bruising.—Two patients developed a mild spontaneous bruising. This is a classical feature of Cushing's syndrome. Robson and Duthie (1950), however, have observed that cortisone increases capillary resistance, in which case bruising would not be expected to occur.

Menstrual Irregularities.—The intervals between menstrual periods increased slightly in four cases without other symptoms. In Case 4 menstruation ceased after the second month of treatment, and amenorrhoea persisted until after treatment was suspended on account of the development of a "moon face," to which the patient objected on aesthetic grounds.

Oral Paraesthesia and Enlarged Submandibular Glands.—Cases 7 and 8 developed paraesthesia in their tongue and cheeks. Case 7 developed small buccal ulcers which disappeared without treatment. Case 8 has developed bilateral swelling of her submandibular glands. They are not painful, but are associated with a dryness of the mouth.

Steroid Metabolism Studies

A large number of estimations were carried out during cortisone administration. These are too voluminous to publish in detail, and the following is a summary of the main findings.

Corticoids.—The pre-treatment values of urinary form-aldehydogenic steroid excretion in four cases were below the normal range for the method—namely, 0.4–1 mg./24 hours. On treatment with cortisone (100 mg./24 hours) a small increase into the normal range was observed. A further increase to levels exceeding the normal range was noted when the daily dose of cortisone was increased to 200 mg.

17-Ketosteroids.—In the seven cases studied, pre-treatment levels of 17-ketosteroid also tended to be at the lower limit of the normal range. The inception of treatment in all

FIG. 3.—Differential analysis of alcoholic 17-ketosteroids.

cases investigated was associated with an initial fall in 17-ketosteroid excretion. On prolonged administration those cases having a relatively high pre-treatment 17-ketosteroid output continued to excrete reduced amounts, while in those cases with a low pre-treatment output excretion rose above pre-treatment levels. In the three cases in which a differential analysis of 17-ketosteroids was attempted (Fig. 3) there was an increased excretion of steroids with the 11-oxy-function—possibly catabolic products of the administered cortisone. In two of these cases, and in others not reported here, the ratio of etiocholanolone/androsterone excreted was significantly raised compared with normal subjects, although this is not necessarily of particular significance to rheumatoid arthritis (Robinson and Goulden, 1949). In no case was the raised etiocholanolone/androsterone ratio restored to normal during the treatment with cortisone; on the contrary, there was a further relative and absolute increase in etiocholanolone in two cases.

Haematological Investigations

Three cases were investigated in detail (Nos. 5, 6, and 9), including observations on all types of cell in the peripheral blood and bone marrow, and serial readings of the sedimentation rate.

Peripheral Blood

Haemoglobin and Erythrocytes.—In all three cases an increase in reticulocytes was noted during the second week of treatment, and this was followed by a rising haemoglobin and red-cell count until normal levels were reached. At the same time the cells showed a full complement of haemoglobin, and microcytosis, if it had been present, disappeared.

The Leucocytes

Eosinophils.—The administration of cortisone resulted in a diminution of 60–70% in the number of circulating eosinophils in all cases. In two cases this effect was obtained in the first 24–48 hours, but in the third case the lowest level was not reached until the fifth day. In two cases the eosinophils “escaped” to levels much above the original in two to four weeks. This phenomenon was also observed in five other patients treated with cortisone on whom eosinophil counts were performed but which were not studied in detail. In Case 9 the eosinophils returned transiently to their original level—the marked and sustained increase noted in the other cases not being present.

Total Leucocytes.—In all cases the total count rose and a leucocytosis was observed at some stage. This contrasts with the low normal or subnormal level before treatment. The neutrophil granulocytes showed the most spectacular rise, but the lymphocytes and monocytes showed some small increases also. A lymphopenia was not observed at any stage.

Blood Platelets.—The changes in the blood platelets were not so dramatic as in the leucocytes. Generally speaking, the count appeared to follow the granulocytes—rising and falling with the level of these cells.

The Bone Marrow

The bone marrow was studied in each case by repeated sternal punctures. Initially, the bone marrow showed some increase in plasma cells—a fact which had previously been noted by Hayhoe and Robertson-Smith (1951). After the beginning of treatment the most marked change was an increase in the number of cells of the marrow. This increase in number applied to all types of cells, but particularly the granulocytes. The number of plasma cells appeared to decrease, but this was probably a relative rather than an active diminution due to an increase in the number of the other cells. In the most anaemic case (No. 6) a marked erythroid hyperplasia was also noted during the second week of treatment.

The number of eosinophils in the marrow varied considerably from time to time, though they probably decrease slightly at first but later increase.

The Plasma Volume

During treatment all patients showed some degree of fluid retention as studied by fluid-balance estimations and increase in weight. In Case 6, pitting oedema of dependent parts was noted. At the same time plasma-volume studies showed a decrease. These changes were observed in all three cases, but were most marked in Case 6, in which the results were as follows:

Date	Plasma Volume	Hb	P.C.V.
16/4/51	3.6 litres	60%—8.7	29%
27/4/51	2.0 "	80%—11.6	38%
8/5/51	2.0 "	86%—12.5	40%
12/6/51	2.2 "	87%—12.6	40%
21/6/51	2.4 "	88%—12.8	41%
13/9/51	3.5 "	90%—13.0	40%
29/9/51	3.5 "	88%—12.8	39%

It will be seen that, initially, during the period of rapid change the haemoglobin and packed-cell volume showed similar variations to the plasma volume. But, as the latter returned to its normal level rather slowly, the red cells, etc., had increased and no change was seen. The period of maximum oedema appeared to coincide with the minimum plasma volume. At the same time serum potassium levels fell from 19 mg. to 10.6 mg. per ml.—the lowest level being reached when oedema was at its height.

Effect on Serum Antibodies

The effect of cortisone administration on serum antibodies was also studied, and for this purpose the following antibodies were chosen: (1) naturally occurring alpha and beta antibodies, one or both according to the group of the case; (2) antistaphylococcal toxin titres; (3) Rose's differential agglutination titre; and (4) antistreptolysin O titre.

Among the first three groups of antibodies studied no significant change in titre was noted in any case. In two cases no change in the antistreptolysin titre was observed, but their titre was low at the beginning of treatment. In the third case (No. 6) the titre was high before treatment and the level fell from 700 units to 300 units per ml. at the end of the period of observation.

The Sedimentation Rate

Both Wintrobe and Westergren techniques were used. There did not seem to be any great difference between them, but the impression gained was that the Wintrobe was probably the more sensitive. In rheumatoid arthritis treated with cortisone, it must be emphasized that the actual level of the sedimentation rate does not appear to be of great importance, particularly in the case of the Westergren method. Thus cases which are clinically active and with numerous manifestations of the disease may have sedimentation rates only slightly above normal levels. Further, cases which are clinically progressing favourably may show a raised figure.

In this short study it was noticed that there seemed to be some correlation with the clinical condition if the general trend was noted. Thus cases which are deteriorating show a rising rate and cases improving show at first a falling rate which later flattens out and remains more or less steady, though sometimes at a figure greatly in excess of the conventional “normal.” On the results so far, it would appear that the trend, rather than the absolute level, is much more significant, and if this is noted it is capable of giving some indication of the progress of the case. But the clinical assessment still remains the most important, as an intercurrent infection may raise the sedimentation rate quite independently and possibly without affecting the arthritic condition.

Discussion

It is apparent from this series of cases that the manifestations of active rheumatoid arthritis can be suppressed by the administration of cortisone. We have not encountered any case in which rheumatic symptoms are resistant to adequate doses of cortisone, and we have been impressed by the consistency of the clinical

FIG. 4.—Case 5. Haematological responses with cortisone.

response as compared with the variability of the metabolic and other effects of cortisone (Browne, 1951). Where permanent damage is absent or moderate patients can eventually be returned to their own work, or to some form of lighter work, and women will be able to undertake most household duties. However, in almost every case administration has to be continued indefinitely to maintain this suppressive effect, although it seems likely that in the occasional case—for example, Case 1—cortisone can precipitate a remission of symptoms of considerable duration, and we have seen and heard of other such cases.

The success of cortisone treatment depends upon careful selection of cases and is much influenced by the difference between the suppressive dose and the "toxic" dose. This varies greatly from patient to patient and cannot be predicted in any given case.

Where the margin is large, as for example in Case 3, cortisone administration is both simple and highly satisfactory; where it is small (Case 4) it may be extremely difficult to achieve and maintain the balance between the control of symptoms and the incidence of undesirable side-effects.

Nevertheless we are of the opinion that there is a tendency at the moment to attach too great significance to mild side-effects, such as facial rounding and slight irregularity of the menstrual cycle. For instance, the incidence of side-effects reported by Ward *et al.* (1951) was 63% of 21 cases treated by 75 mg. or more of oral cortisone daily, though all these side-effects were reversible and none necessitated the discontinuance of treatment. The preoccupation of many observers with these mild side-effects reminds one of a house-proud woman overconscious of a speck of dust which the visitor has not noticed.

It would appear from our series that no single-cell type of blood investigation is of much value as a method of controlling treatment. Indeed, the changes observed in the blood all appear to be secondary to the general effect of the drug on the body as a whole—the changes in the blood being indirect. Apart from the first few days of treatment, eosinophil counts are unreliable and their level would seem to have little or no bearing on the clinical progress of the case. The remaining blood changes, if viewed as a whole, may, however, give some indication. The sedimentation rate is of some help, but even here it is the general trend rather than the absolute level which must be noted. Any sustained or sharp increase heralds deterioration in the clinical condition. Any marked and sustained fall in the erythrocyte, leucocyte, or haemoglobin levels, particularly that of the granulocytes, coincides or precedes a clinical deterioration, but the correlation is not absolute and is in the nature of a pointer—a danger signal. The clinical assessment still remains the best and most reliable guide to progress.

The discovery of this form of treatment emphasizes the importance of the early diagnosis of rheumatoid arthritis. It is probable that the results achieved in our series, in which we purposely excluded very early cases, could have been further improved—on a lower dosage and therefore with fewer side-effects—if earlier cases without joint damage had been selected. Cortisone will have little effect where extensive joint damage is present, and may be dangerous in view of the high dosage required to obtain a small amelioration of symptoms.

Until the significance of cortisone's side-effects is more fully understood, our aim should be to maintain the patient in a state in which he remains reasonably comfortable. We do not consider it advisable to attempt to suppress the symptoms of rheumatoid arthritis completely when this requires a high maintenance dosage.

Summary

Twenty selected cases of active rheumatoid arthritis have been studied during prolonged cortisone administration and have been separately assessed from the clinical, haematological, and metabolic aspects.

In 17 cases the patient has been enabled to return to previous work or household duties.

In only one case has it been possible to stop administration.

Certain methods of dosage have been assessed and side-effects have been studied.

The cortisone used in this study was provided from a generous gift made jointly to the Medical Research Council and the Nuffield Research Foundation by Messrs. Merck & Co., Inc. We wish to acknowledge the valuable assistance given to us by Dr. B. Gottlieb, consultant physician, St. Mary Abbots Hospital, and his assistants, and by the following pathologists and biochemists and their assistants: Dr. H. E. Archer and Dr. R. G. L. Waller, West London Hospital, and Dr. A. G. Signy, St. Mary Abbots Hospital.

SICKLE-CELL TRAIT IN SOUTHERN INDIA

BY

H. LEHMANN, M.D., Ph.D.

Department of Pathology, St. Bartholomew's Hospital,
London, E.C.1

AND

MARIE CUTBUSH, B.Sc.

When the traveller in East and Central Africa inquires from the inhabitants about their distant past, they will often tell him of tall men, fairer than themselves, bearded and with long hair, who came from afar bringing codes of law, handicrafts, and cattle.

Several leading anthropologists have speculated whether there were migrations to prehistoric Africa from other continents, possibly Asia. Such speculations have been supported by the observation that the tall, broad-shouldered skeleton of the modern Bantu appears only in Neolithic excavations, whereas the types found in older strata are more slender. It had been noted that, with the exception of the Ankole herds, which are related to those of ancient Egypt, the East African cattle show a resemblance to the Indian cow. Similarities are also found between the poultry of Africa and India.

Fortunately for anthropologists the present-day inhabitants of Africa possess distinctive features in their blood—the sickle-cell trait, a very high incidence of a particular combination of Rh antigens known as R_0 (cDe), and another blood-group antigen provisionally referred to as He. So far as we know, the sickle-cell trait and sickle-cell anaemia have not been reported in people who were not either Africans or members of groups which must be expected to have an admixture of African blood. For example, Negro slaves undoubtedly mixed with Mediterranean races in Roman times. The sickle-cell trait has not been found in races which do not also show a raised incidence of the gene combination R_0 (cDe) (Mourant, 1951). This combination is found comparatively rarely in Northern and Central Europe and in Northern India, with a frequency of approximately 2%. By contrast, it has a frequency of over 50% in all African populations south of the Sahara so far tested. It is distributed fairly evenly all over tropical Africa, regardless of the incidence of the sickle-cell trait (Wiener, 1946; Boyd, 1950; Ikin and Mourant, 1952). The antigen here called He has been detected in about 5% of West Africans but has not been found in the course of testing about 1,000 Europeans (Ikin and Mourant, 1951, 1952).

It seemed possible that an investigation of the blood of certain Southern Indian communities might serve to refute or support the idea of a racial link between Africa and India. The aboriginal tribes were chosen as the group in whom a search for African blood features appeared most likely to yield positive results.

There is no general agreement how the peoples of South India should be classified. They have in the past often been divided into settled communities, or Dravidians, and aborigines, or Pre-Dravidians, but there are objections to this on both linguistic and cultural grounds; nor does the division correspond clearly to anything in the history of these populations. The so-called Pre-Dravidians of the Nilgiri Hills vary from

civilized agricultural communities such as the Badagas (who have affiliations with the Canarese) to tribes such as the Irulas, Kurumbas, and Paniyans, who are found living under primitive conditions in the jungle.

Materials and Methods

Three aboriginal communities—the Badagas, the Todas, and the Irulas—were investigated. Sex, approximate age, and relationship to other persons tested were noted. To determine the incidence of the sickle-cell trait each blood sample was examined after incubation with a 2% sodium metabisulphite solution (Daland and Castle, 1948). Blood samples were collected from 60 Todas, 60 Badagas, and 80 Irulas for the determination of blood groups in the following systems: ABO, MNS, Rh, Duffy, P, and for the detection of the He antigen.

A control group of other peoples was investigated for the sickle-cell trait.

Results

The sickle-cell-trait incidence among 191 unrelated Badagas was 8.4%, among 60 Todas 3.3%, and among 80 unrelated Irulas 30%. No sickle-cell trait was found among 443 unrelated members of other communities of the region (see Table).

The Incidence of the Sickle-cell Trait in Some South Indian Communities (With the exception of the Todas, all individuals are unrelated)

Population	Number Examined	Sickle-cell Trait	
		Number of Individuals	%
Irulas	80	24	30
Badagas	191	16	8.4
Todas	60	2	3.3
Tamils	128	0	0
Malayalis	111	0	0
Canarese	95	0	0
Telegus	109	0	0

All first-degree relations have been excluded from the Table, except in the case of the Todas. As the whole Toda community numbers fewer than 500 individuals, practising polyandry, it was impossible to exclude close relatives. However, the 60 samples were collected from seven widely separated settlements; the two sickle-cell-trait carriers were children living in settlements some miles apart.

The incidence of the Rhesus chromosome R_0 (cDe) was at the low level found in Europeans and Northern Indians; rather than at that found in Africans. Among 60 Badagas, 2 individuals were of the phenotype R_0 or ccDce; among 60 Todas, 2; and among 80 Irulas, none.

None of the 120 blood samples contained the He antigen.

Discussion

These findings lend support to the idea of an Indian migration to Africa in prehistoric times. The reverse possibility—an influx of African blood bringing the sickle-cell trait to the hills of Southern India—should have resulted in a raised incidence of the gene combination R_0 (cDe). The fact that the incidence of R_0 is high everywhere among the negro races of Africa, whereas the incidence of the sickle-cell trait shows wide variations among them, suggests that Africa received the sickle-cell trait at a period too recent to allow an even distribution over the continent. It is realized that there are other possible interpretations of the above results.

It is not suggested that the actual migrants to Africa were Badagas or Todas or even Irulas. The first came from the North to the Nilgiri Hills only within the last 1,000 years; the second, though allegedly autochthonous, resemble Europeans in appearance and in their possession of the subgroup A_2 and of the Rh genotype rr (cde/cde). It is likely that at least the Badagas and Todas received the sickle-cell trait from older Southern Indian communities.

The examination of "pre-Dravidian" people is being continued with the hope of further defining the distribution of the sickle-cell trait in Southern India. However, the main purpose of the investigation has been achieved since the results lend support to the possibility of a link between prehistoric Africa and India.

Summary

The sickle-cell trait was found to be present in a number of individuals belonging to three aboriginal communities of Southern India. There was a low incidence of the Rh chromosome R_0 (cDe).

No sickle-cell-trait carrier was discovered among a control group of the non-aboriginal or "Dravidian" population.

The possible anthropological significance of these findings is discussed.

We should like to thank the Minister of Health of the Government of India and the Secretary of the Indian Council of Medical Research for making the necessary arrangements for these investigations. We are especially indebted to Dr. V. N. Patwardhan, Director of the Nutrition Research Laboratories, Coonoor, and to Dr. N. Veeraraghavan, Director of the Pasteur Institute, Coonoor, for generously allowing us laboratory facilities. We also wish to thank Dr. A. E. Mourant, of the Blood Group Reference Laboratory, London, for supplies of testing sera. The expenses of this work were generously defrayed by the Nuffield Foundation.

THE SICKLE-CELL TRAIT IN WESTERN NIGERIA

A SURVEY OF 1,881 CASES IN THE YORUBA

BY

D. B. JELLIFFE, M.D., M.R.C.P., D.C.H.
D.T.M.&H.

AND

JOHN HUMPHREYS, M.B., Ch.B.

(From the Department of Medicine, University College,
Ibadan, Nigeria)

Yorubaland occupies the greater portion of Western Nigeria, lying between the Lagos lagoon in the south, the River Niger in the north, the Dahomey frontier in the west, and the Benin country in the east. Ibadan itself is a huge sprawling city of mud-brick buildings. The population, which is mainly Yoruba, is in the region of half a million. Ibadan's present importance is due to the fact that it lies at the centre of the cocoa-growing area of Nigeria, although it has been the site of a considerable town for over a hundred years.

The Yoruba are for the most part peasant farmers and petty traders. Their diet is largely vegetarian, the staple farinaceous foods being yams, maize, and cassava. Animal protein is deficient in the food of the majority, as cattle cannot be reared locally but have to be brought for slaughtering from northern Nigeria.

Groups Examined

In this survey 1,881 Yoruba were examined. The majority were from Ibadan, although some came from all parts of Yorubaland. Sickling was looked for by the method of

Sketch map of Nigeria showing area of survey

Scriven and Waugh (1930), although no preliminary congestion was used. The finger was pricked and a drop of blood transferred to a coverslip. This was inverted and placed face downwards on a clean slide. The coverslip was ringed with petroleum jelly and the preparation examined for sickling after 72 hours. In a few, the enclosed blood became either haemolysed or dried. These cases were not included in the series.

It is felt that the cases reviewed here represent a fair cross-section of the Yoruba population of Ibadan. The newborn babies were examined in the maternity wards and the other infants while attending welfare clinics. The older pre-school children and the elderly were difficult to test in large numbers. The few that were examined were in-patients, out-patients, or visitors at hospital. The three groups of schoolchildren were tested at several schools serving a wide area of the town. The young adult male group was the least balanced, as the majority were either policemen or Army recruits, and were probably of more than average physical development.

Results of the Survey

The results are shown in Table I. The average incidence in the whole series of 1,881 was 23.7%. As can be seen, no case of sickling was observed in any of the 51 newborn babies examined. The possible significance of this is discussed later. In the other groups the incidence of sicklaemia

TABLE I.—Results of Survey for the Sickle-cell Trait in 1,881 Yoruba

Age	No. Examined	No. Positive	% Positive
1st 2 weeks	51	None	—
Over 2 weeks to 1 year	120	30	25.0
" 1 year to 4 years	60	17	28.3
" 4 years, " 8 "	301	84	27.9
" 8 " " 15 "	512	133	25.0
" 15 " " 18 "	144	30	20.9
Young adult males	302	58	19.2
females	339	80	23.6
Older adults (males and females)	52	14	26.9
Total	1,881	446	23.7

varied from 19.2% in young adult males to 28.3% in children between the ages of 1 and 4 years. If the first group containing babies up to 2 weeks old is omitted from analysis, a χ^2 test shows that the proportions of positive cases in the other age groups do not vary more than would be expected by chance ($\chi^2=8.83$). For 7 degrees of freedom P lies between 0.3 and 0.2. In other words, the sickle-cell trait would appear to occur with equal frequency at all ages, with the exception of the newborn.

Discussion

Comparatively few surveys for the sickle-cell trait have been undertaken in tropical Africa, and results in different countries vary. Thus, 45% of the pygmyoid Baamba show sickling (Lehmann and Raper, 1949), while Sarmento (1944) found only 8% positive in a survey of adult males in

Angola. It is, however, correct to say that most investigators have found from 15 to 30% to show sicklaemia, so that the findings in the present series are in rough accord with observations made elsewhere.

As has been stressed by several authors (Raper, 1950), the sickle-cell trait is common in tropical Africa, while sickle-cell anaemia is rarely recorded. This is in contradistinction to findings in American negroes, in whom the sickle-cell trait is much less common (6-9%), but in whom sickle-cell anaemia is frequently seen. It has been estimated that in America the ratio of sickle-cell anaemia to trait is 1:50, while Raper (1950) estimates that the ratio in Africa must be below 1:1,000. The explanation of this undoubted fact is unknown. Raper suggests that it may be connected with genetic modification produced by intermarriage with Caucasians in the case of the American negro. However, as has been pointed out elsewhere (Jelliffe, 1952), it must be realized that a partial explanation for the rare reports of sickle-cell anaemia in Africa lies in the comparatively few doctors and laboratories in these regions, together with a lack of awareness of the disease entity and the difficulty of making a rapid and certain diagnosis, especially in view of the numerous other forms of anaemia which occur so commonly in indigenous Africans. The possibility that sickle-cell anaemia may be more frequent than has hitherto been suspected is suggested by Jelliffe and by a recent report from Kenya (Foy, Kondi, and Brass, 1951).

At the present state of knowledge, it nevertheless seems certain that sickle-cell anaemia is relatively rare in tropical Africa, despite the presence of an enormous population showing the sickle-cell trait. This is confirmed by the present survey. Of the 1,881 cases examined, none were observed to have an obvious haemolytic anaemia, although this cannot be regarded as scientific evidence, as neither careful clinical examinations nor full haematological investigations were undertaken. However, it is significant that, during the past nine months in Ibadan, where there must be over 100,000 persons with the sickle-cell trait, only 12 cases of sickle-cell anaemia have been seen.

The mode of inheritance of sickle-cell anaemia and its relation to the sickle-cell trait is still far from certain. The most recent suggestion (Neel, 1949) is that sickle-cell disease may be due to a gene which in a homozygous condition produces sickle-cell anaemia and in the heterozygous condition sicklaemia (sickle-cell trait). As Lehmann (1951) has noted, if this theory is correct, sickle-cell anaemia would be expected to occur more frequently in Africa than in America. As he remarks, "One possible explanation for this discrepancy could be that the gene is lethal and that homozygotes die earlier than the rest of the population." If this were the case the incidence of sickling would be expected to fall in the older age groups, whereas the frequency was found to be the same at all ages in three tribes examined in Uganda.

As has been noted previously, in the present series no variation in incidence could be found in the different age groups, with the exception of the newborn babies. This can be interpreted as supporting Lehmann's view that the simple homozygous-heterozygous theory does not appear to fit the facts as seen in tropical Africa. The most interesting feature of this survey was the apparent absence of sickling in newborn children examined in the first two weeks of life. In no instance were sickle-cells seen after 72 hours' observation; and, in order to follow up this type of case more carefully, blood from the last 18 newborn babies was examined again after 216 hours. The results are recorded in Table II. As can be seen, 12 showed no sickling even after this interval, 5 specimens were haemolysed, while 1 case showed the presence of less than 5% sickle cells.

It has recently been shown that the haemoglobin of sickle-cell anaemia and normal haemoglobin differ physico-chemically, and that the haemoglobin of a subject with the sickle-cell trait is a mixture of the two (Pauling *et al.*, 1949). A possible explanation for the absence of sickling in these newborn infants is that sickle-cell haemoglobin is not present

TABLE II.—The Sickle-cell Trait in the Newborn

in foetal blood but develops after birth. Unfortunately, it was not possible to follow up this series of cases. In addition, in the normal subject, foetal haemoglobin has different biophysical properties from adult haemoglobin, although exact differences in chemical structure are still far from clear-cut. However, it is well recognized that foetal haemoglobin has an increased affinity for oxygen and that, conversely, it reduces more slowly. It has been shown by various workers that foetal haemoglobin persists, to a diminishing degree, in the blood of newborn infants, although the length of time it can be detected is uncertain. Periods varying from days to a few months have been described by different investigators (Smith, 1945).

Sickling of red blood corpuscles probably occurs only when haemoglobin is in a reduced state, at least in subjects showing the sickle-cell trait. It seems possible, therefore, that the apparent absence of sickling in the first two weeks of extrauterine life may be due to this persistence of foetal haemoglobin, and that sickling cannot be demonstrated because of the extreme difficulty of causing this type of haemoglobin to become reduced.

In this context it may be mentioned that recent work by Liquori (1951) has shown that in Cooley's anaemia, a disease with many points of similarity to sickle-cell anaemia, 40-60% of the haemoglobin may still be foetal at the age of 8 years. Although this is in contrast to the hypothesis suggested here, nevertheless both findings would seem to indicate that further work on the relation of foetal haemoglobin to sickle-cell haemoglobin is required.

Summary

A survey for the sickle-cell trait was undertaken in 1,881 Yoruba in Ibadan, Western Nigeria. The average incidence was 23.7%. The incidence showed no real variation with age, although no cases of sickling were noted in 51 newborn babies. The latter was thought to be related to a persistence of foetal haemoglobin into the first weeks of extrauterine life. The results of the survey are discussed, with especial reference to the homozygous-heterozygous theory of inheritance of the sickle-cell trait.

Thanks are due to Professor A. Brown, of the Department of Medicine, University College, Ibadan, for permission to publish this paper.

IRON AND THE "PHYSIOLOGICAL" ANAEMIA OF PREGNANCY*

BY

NANCY BENSTEAD, M.B., B.S.

AND

G. W. THEOBALD, M.D., M.R.C.P., F.R.C.S.Ed.
F.I.C.S., F.R.C.O.G.

(From St. Luke's Maternity Hospital, Bradford)

The volume of the vascular bed increases during pregnancy, necessitating a commensurate increase in the blood volume. Dieckmann and Wegner (1934) found that the total blood volume was increased by 23% during pregnancy, and that, although this increase was proportionately much greater in the plasma content, the cellular element was also increased. Since the haemoglobin level tends to return to normal values during the puerperium there would appear at first sight to be a *prima facie* case for the assumption that the anaemia of pregnancy is physiological and for the acceptance of the minimal normal figures of: haemoglobin 10 g.%, erythrocytes 3,360,000, and a packed cell volume of 33%, which were suggested by Adair, Dieckmann, and Grant (1936). On the other hand, many investigators deny that haemodilution can cause such low figures as those quoted above, and believe that the so-called physiological anaemia of pregnancy denotes a marked deficiency of iron.

Before animadverting upon the conflicting reports in the literature it is desirable to see the main factors of the problem in perspective. They are: the level of the maternal haemoglobin before pregnancy occurs, the cessation of menstruation during pregnancy, the increased blood volume, and the foetal demand for iron.

Davies *et al.* (1946), in a survey of 2,000 women in the London region, found that anaemia was encountered twice as often in married as in single women, and there is evidence, particularly that emanating from the blood transfusion services, that anaemia is more widespread in England in 1951 than it was in 1946. Strauss and Castle (1932), Strauss (1934), Corrigan and Strauss (1936), Linder and Massey (1939), Young *et al.* (1946), Laurell (1947), Cartwright and Wintrobe (1949), Lundström (1950), and Ventura and Klopfer (1951) are all of the opinion that there is manifested during pregnancy a tendency towards anaemia which is commonly caused by iron deficiency. Davidson and Fullerton (1938) showed that the saving of iron due to the cessation of menstruation failed to counterbalance the loss of iron to the growing foetus, and maintained that the normal pregnant woman is dangerously near to iron starvation. Whitby and Britton (1942) assert that an erythrocyte count below four millions is pathological, and Vaughan (1936) doubts whether an anaemia which responds to iron can be physiological.

On the other hand, Wolff and Limarzi (1945) regard a normocytic normochromic anaemia occurring during pregnancy as physiological and, together with Rath and Finch (1949), consider it unnecessary to give iron to pregnant women unless there is evidence of patho-

logical anaemia. Some observers, indeed, regard the lowered blood viscosity associated with the hydraemia of pregnancy as mechanically advantageous, and it is true that the loss of haemoglobin during delivery is thereby lessened.

Adair *et al.* (1936) and Evans (1943) go further and aver that iron administered during pregnancy fails to maintain the normal level of haemoglobin. Dieckmann *et al.* (1950) have more recently shown that the addition of molybdenum renders the iron more efficacious, and in an earlier paper Dieckmann *et al.* (1949) showed that even in cases of true anaemia of pregnancy the haemoglobin can be raised from 9.9 to 11.8 g.% by this modified form of iron therapy.

The Present Investigation

This clinic serves a large industrial area in the centre of the heavy woollen industry. The purpose of the investigation was to report: (1) the incidence of anaemia in patients attending the antenatal clinic; (2) the results obtained by administering iron from the 16th week of pregnancy until term; (3) the results obtained by administering iron for eight weeks only, beginning at the 24th week of pregnancy; and (4) whether the addition of a small amount of molybdenum increases either the absorption or the utilization of iron.

All the patients who participated in the following investigations were in the third decade of life, and each group was carefully matched according to age, parity, previous health, and home conditions. They were all reasonably healthy, and each case was carefully supervised by one of us (N. B.), who got to know each woman personally.

All these women took four *tabellae calcii cum vitamino D* (N.F.) daily. Each tablet contained calcium sodium lactate, 7½ gr. (488 mg.), calcium phosphate, 2½ gr. (163 mg.), and calciferol 1/4,800 gr. (0.014 mg.), which is equivalent to 500 international units of vitamin D. They also took the extra rations and vitamins supplied by the Ministry of Food.

Experiment 1.—Seventy-two patients at or before the 16th week of pregnancy whose initial haemoglobin levels were not below 11 g.% were divided into two matched groups—A and B, the latter being the control group. *Group A* took iron in the form of *tabellae ferri sulphatis compositae* (N.F.), two tablets thrice daily. Each tablet contained: excised ferrous sulphate, 3 gr. (195 mg.), copper sulphate, 1/25 gr. (2.4 mg.), and manganese sulphate, 1/25 gr. (2.4 mg.). *Group B (Control)* took a mixture known as "mist. antenatal," which was made up to the following prescription:

Syrup	20 min. (1.2 ml.)
Glycerin	10 min. (0.6 ml.)
Blackcurrant flavouring q.s.	
Aqua	to 1 fl. dr. (3.5 ml.)
1 fl. dr. (3.5 ml.) to be taken twice daily.	

Experiment 2.—Thirty patients at or before the 16th week of pregnancy whose initial haemoglobin levels were not below 11 g.% were divided into two matched groups C and D. *Group C* took *tabellae ferri sulphatis compositae* (N.F.), two tablets thrice daily for eight weeks, beginning at the 24th week of pregnancy. *Group D* took White's "mol-iron" tablets,* two thrice daily for eight weeks, beginning at the 24th week of pregnancy. Each tablet contained ferrous sulphate, 3 gr. (195 mg.), and molybdenum oxide, 1/20 gr. (3 mg.).

Methods of Blood Examination

Investigations were carried out at monthly intervals until term, and again on the sixth day of the puerperium. The estimations made were the haemoglobin and the packed cell volume, from which was calculated the mean corpuscular

*The expenses of this investigation were defrayed by a grant from the Endowment Fund generously afforded to one of us (G. W. T.) by the Bradford Hospital Management Committee (A), to whom we express our grateful thanks.

*These tablets, similar to those used by Dieckmann *et al.*, were most generously sent to one of us (G. W. T.) free of all cost through the kindness of Dr. H. A. Strade, of the Medical Department of Messrs. White Laboratories, Inc., Newark, New Jersey.

haemoglobin concentration. The haemoglobin was estimated by means of a Sahli colorimeter (standard 14.8 g. = 100%). This was calibrated at the beginning of the experiment and recalibrated six months later. The packed cell volume was estimated by Wintrobe's method.

The initial haemoglobin estimations used in Fig. 1 were made by the pathological laboratory of St. Luke's Hospital, and were estimated by means of a "unicam" photoelectric colorimeter. The remaining blood examinations were carried out by one of us (N. B.) not more than 30 minutes after collecting the blood.

FIG. 1.—Distribution of the initial haemoglobin values of the 2,000 consecutive antenatal patients mentioned in the text.

The initial haemoglobin estimations of 2,000 consecutive cases, all less than 16 weeks pregnant, attending the booking-in clinics from January to October, 1950, were as follows (see Fig. 1):

40.15%	had readings of 12 g. or more per 100 ml.
59.85%	" " " below 12 g. " " "
37.25%	" " " 11.5 g. " " "
18.85%	" " " 11 g. " " "
12.05%	" " " 10.5 g. " " "
6.55%	" " " 10 g. " " "

Notes on Statistical Analysis of Experiments.—The standard error of the difference between the means was calculated by using the second method described by Bradford Hill (1948), and, in order to facilitate these calculations, the haemoglobin estimations are all reported as percentages. Where the difference between the means (D.M.) is greater than twice the standard error of the difference between the means—that is, $D.M./S.E.D.M. > 2$ —it is regarded as significant.

Discussion of Results

It is a matter of no little concern that 6.5% of 2,000 consecutive patients attending this clinic were severely anaemic at the 16th week of pregnancy, before any significant haemodilution had occurred, and that about 60% of all cases showed readings below 12 g.%. The normal range for adult non-pregnant women is regarded by Whitby and Britton as lying between 12 and 15.5 g.%. The results reported in Figs. 2 and 3 and in Tables I to III vary significantly from those published by most other

FIG. 2.—Experiment 1. (a) Shows the arithmetic means of the haemoglobin values plotted at four-weekly intervals in group A and the control group B. (c) The curves denote the arithmetic means of the mean corpuscular haemoglobin concentration of groups A and B at the same time intervals.

authors. It will be seen that the adequate administration of iron makes it possible for normal haemoglobin values to be maintained throughout pregnancy, whereas if the woman does not take iron she begins the puerperium with a significantly lessened amount of haemoglobin.

This latter observation is all the more important when it is realized that the average initial haemoglobin value for the control group (B) was 88.8%, which means that the subjects chosen for the investigation were almost exclusively recruited from 40% of those who booked at the clinic (see Fig. 1).

Similar advantages are observed in the mean corpuscular haemoglobin concentrations from taking iron throughout pregnancy, but although the differences between the two

FIG. 3.—Experiment 2. (a) Shows the arithmetic means of the haemoglobin values for groups B (control), C, and D plotted at four-weekly intervals. (c) The curves show the arithmetic means of the mean corpuscular haemoglobin concentration of the same three groups at identical intervals of time.

groups on the sixth day of the puerperium are significant; it will be noted that the value for the 16th week of pregnancy in the control group is almost identical with that for the sixth day of the puerperium.

It is certainly a matter of interest that the administration of iron for eight weeks only, beginning at the 24th week of pregnancy, causes a rapid recovery from the commencing "physiological" anaemia, and that thereafter satisfactory normal blood values are maintained. It will be observed that all the figures for the sixth day of the puerperium are higher in groups C and D than in Group A.

This investigation provides no evidence to support the contention of Neary (1946), Chesley and Annitto (1948), and Dieckmann *et al.* (1949), that molybdenized iron is more

efficacious than ferrous sulphate in either the treatment or the prevention of anaemia during pregnancy. On the other hand, the important observation made by both Neary (1946) and Chesley and Annitto (1948) that molybdenized iron is more easily tolerated has been amply confirmed. It was found that 33% of the patients in group A and 40.2% in group C found it difficult or impossible to tolerate ferrous sulphate tablets, and it can be assumed that between 30 and 40% of all antenatal patients will not, in fact, take these tablets if they are routinely prescribed in the antenatal department. The mol-iron tablets were tolerated by 86% of the patients in group D and were equally well tolerated by other patients not included in the experiment (Table IV). It must, however, be borne in mind that the old scale preparation

ferri et ammonii citras was even better tolerated and proved equally efficient. The mol-iron tablets are easier to prescribe and to take than this latter preparation, but the increased expense involved and the world shortage of molybdenum may delay the routine use of these tablets (which are now made in England). The important point to realize is that many pregnant women cannot tolerate ferrous sulphate pills and therefore do not take them.

This investigation suggests that a high percentage of pregnant women in Bradford suffer from iron deficiency, and that the administration of iron together with calcium and vitamin D prevents both the microcytic and the "physiological" anaemia of pregnancy. An idea to be considered further is whether iron deficiency may in some way be associated with the occurrence of miscarriage and hypertension (see Table V). The only disadvantage of maintaining the haemoglobin level at its normal value throughout pregnancy would

TABLE V.—Additional Observations

Group	Miscarriage	Hypertension (Blood Pressure Exceeding 140/90 mm. Hg on at Least 2 Occasions)	Post-partum Haemorrhage—More than 20 fl. oz. (570 ml.)
A	—	—	3 (one required blood transfusion)
Control (B)	2 { 18 weeks	5 (1 eclampsia)	1
C	28 " "	1	1 (required blood transfusion)
D	—	1	1

appear to be a slightly increased risk of post-partum haemorrhage. We therefore conclude that the so-called "physiological" anaemia of pregnancy is in reality the expression of iron deficiency, and that the diet in Bradford, and probably in many other centres, is and is likely to remain deficient in this mineral. It would clearly be important to see whether the controlled administration of iron to a much larger group of women would decrease the high incidence of hypertension in pregnant women in Bradford, and whether the maintenance of the normal haemoglobin level throughout pregnancy is associated with the accepted figure for the increase in blood volume.

Summary and Conclusions

A review of haemoglobin readings obtained from 2,000 consecutive cases at or below the 16th week of pregnancy showed that about 60% were subnormal, and that 6.5% of the women were severely anaemic.

The changes in haemoglobin and packed cell volume readings which occurred during pregnancy in matched groups of young healthy women lead us to conclude that: (a) the "physiological" anaemia of pregnancy is associated with a low or subnormal mean corpuscular haemoglobin concentration; (b) normal (non-pregnant) blood values are maintained if therapeutic doses of ferrous sulphate are administered throughout pregnancy; and (c) the administration of ferrous sulphate, or of molybdenized iron, from the 24th to the 32nd week of pregnancy, results in recovery from the commencing "physiological" anaemia, followed by maintenance of normal (non-pregnant) blood values.

The mol-iron tablets were not found to be more efficacious than ferrous sulphate tablets either in preventing or treating the "physiological" anaemia of pregnancy, but they were better tolerated. We would suggest

that ferrous sulphate is not a suitable preparation for the routine administration of iron in antenatal clinics.

We think that the controlled administration of iron to a large group of women should be undertaken in order to see whether the incidence of hypertension would thereby be lessened. It would also be of interest to determine whether the maintenance of the normal haemoglobin level throughout pregnancy is associated with the accepted value for the increase in blood volume.

We would like to thank Dr. R. G. Paley, of the department of medicine at Leeds University, who kindly studied the scheme and made most valuable suggestions from the statistical point of view.

HAEMOGLOBIN LEVELS IN ADULTS AND CHILDREN

BY

W. T. C. BERRY, M.D.

P. J. COWIN, M.R.C.S., L.R.C.P., D.P.H.

AND

H. E. MAGEE, D.Sc., M.R.C.P.

(From the Ministry of Health)

This paper reports the results of haemoglobin studies on 245 males and 266 females of adult age employed in clerical and industrial work, on 214 housewives under 60 years, all living in and around London, and on 1,628 boys aged 6, 10, and 14 years living in two Lancashire towns (I and K), one Surrey town (J), and one Gloucestershire town (L) (see Table I). The method was the same as that employed in earlier studies (Magee and Milligan, 1951), except that oxyhaemoglobin was the pigment determined instead of alkaline haematin. As before, many precautions were taken to ensure accuracy—the two photometers were re-checked by the National Physical Laboratory, pipettes were re-calibrated, and blood was drawn by finger-prick after a period of rest, depending on the previous state of activity of the individuals. The findings are expressed as grammes of haemoglobin per 100 ml. of blood, and, for comparison with previous findings, especially those of the M.R.C. 1943 Survey (M.R.C., 1945), as Hb% on the Haldane scale.

Methods of Sampling

Adult males and females were selected at random; a letter was sent to every *n*th person on the roll of employees asking if he or she would co-operate; the refusal rate was low. No person of income above £1,000 per annum was included.

For housewives, streets were chosen at random and two constant house numbers in the street were nominated. If for some reason the housewife could not participate the house number adjoining was taken. The refusal rate was low. The tests were carried out in their own homes, and pregnant or lactating women and women over 60 were excluded, but no woman was excluded on the grounds of apparent ill-health. However, some housewives excused themselves from participating on health grounds. They numbered one-seventh of all refusals. Since, so far as we could judge, ill-health of a comparable degree existed among those housewives whose haemoglobin levels are reported here, we think that there is no bias from this cause.

For boys, the whole school population of the age groups 6, 10, and 14 years in certain schools, chosen for convenience, were examined.

Results

Adult Males.—The mean haemoglobin level in clerical workers was slightly higher than that in manual workers (Table I). But the difference is not statistically significant, since it is less than twice its standard error. All three means are higher than those obtained in similar people in the 1943 Survey—102%. The higher value for the clerical workers in the present survey is in harmony with the findings of Adcock *et al.* (1948), who obtained higher values in sedentary men than in those of similar age receiving similar diets but engaged in more strenuous occupations—for example, the mean level for the Foot Guards was 99.9% and for R.A.M.C. hospital workers 103%. Adcock *et al.* did not make similar comparisons for women engaged in different occupations.

Adult Women.—The values obtained in the present survey for women show no consistent differences between the clerical

and the manual workers, but it should be remembered that the occupation of the manual workers was far from strenuous. Taking the three groups of women (D, E, and F) as a whole, they compare favourably with the 1943 means for women manual workers and for unmarried women—92.5 and 94.4%, respectively.

Blood Donors.—There were 15 men and 28 women in the above groups (A–F) who had been blood donors for the National Blood Transfusion Service. Their mean haemoglobin levels were 104% for men and 94% for women. Among these were two men with haemoglobin levels of 104 and 111% and six women with levels of 86, 92, 92, 97, 100, and 86% who, for no disclosed reason, had been rejected on the last occasion they presented themselves for bleeding.

Housewives.—The means for the two groups of housewives (Table I) show no differences either between themselves or from the 1943 mean—91.5%. The distribution curve is negatively skewed (see Chart). The S.D. of the two groups is 9.65, which means that on a normal distribution 2.3% of the values would fall below 72.3% and 2.3% above 110.9%. There are no values above 110.9, but 5.6% of the total are below 72.3%. In practically all these women medical reasons for the low haemoglobin levels were elicited by questioning, and all of them were reported to their family doctors.

Percentage distribution of haemoglobin levels in 214 housewives.

Boys.—The haemoglobin determinations on boys were only part of a much more comprehensive survey which involved physical measurements, physical efficiency tests, medical examinations, inquiries into living conditions, and other socio-economic matters. A detailed analysis of the data, which will be published later, shows that where higher mean haemoglobin levels were observed they were merely one facet of a general physical superiority, which was reflected in larger stature, greater weight and strength, and an earlier onset of puberty. Among the socio-economic factors with which these differences were associated, non-dietary as well as dietary factors appear to be responsible. The various haemoglobin values compare favourably with those obtained in 1943 on boys of the same age.

Discussion

It has been suggested that the higher average haemoglobin level in male clerical workers (Group A) than in male manual workers (Groups B and C, Table I) is attributable to the, presumably, more active life of the latter. It might, however, be suggested that the difference is due to higher incomes and presumably better diets of the clerical workers. We were unable to obtain the incomes of Group A, but we found it for most men in Groups B and C. In Group B there was no relationship between income and haemoglobin levels. In Group C the mean haemoglobin of 16 men with incomes at or above £350 per annum was 106.4%, and of 22 men in the same group with incomes at or below £300 per annum, 103.7%. A similar relationship was found for employed women in Group F; 13 of these with incomes of £250 per annum or more had a mean of 94.9%, and 46 with incomes of £200 per annum or less a mean of 91.0%. These numbers are small, and an element of chance cannot, therefore, be entirely excluded. There would seem, however, to be some sort of relationship

between income and haemoglobin level, but this might be explained by the higher-paid workers being older and leading a more sedentary life than the lower-paid ones.

There was no evidence of a difference between the haemoglobin of married and that of unmarried men. Employed married women, on the other hand, had a higher mean level than spinsters in all three groups, D, E, and F, the differences being 0.65, 2.5 and 3.0%, respectively. These differences were found to be independent of income.

In 187 of the housewives the effect of parity could be investigated. Over the range 0-3 children no change in level was found, but the level for mothers of four or more children was well below that of the rest (Table II).

TABLE II.—*Haemoglobin Levels of Housewives According to Parity*

No. of Pregnancies	No. in Sample	Mean Hb % Haldane
0	14	90.2
1	62	91.4
2	64	90.8
3	31	91.7
4 and over	16	86.2

In the study of Magee and Milligan (1951) the haemoglobin of women who had borne three or more children and who were either pregnant or within 65 weeks after labour was lower than in comparable women who had had a smaller number of children. In the present survey all pregnant and nursing women were excluded, and it may be that this effect of repeated pregnancies disappears gradually.

Summary

Haemoglobin levels were determined in 245 adult men and 266 adult women employed in clerical and industrial work, on 214 non-pregnant and non-nursing housewives under 60 years living in and around London, and on 1,628 boys aged 6, 10, and 14 years living in two Lancashire towns (I and K), one Surrey town (J), and one Gloucestershire town (L). The mean findings are set out in Table I.

So far as they are comparable with the M.R.C. survey of 1943 the present findings are about the same or on a slightly higher level. Of the 214 housewives 5.6% had values less than 72.3% (Haldane). Medical reasons for the low levels were elicited by questioning.

Male clerical workers had higher values than male manual workers, a difference attributable to the more active lives of the latter. In some of the groups of men and women a direct relationship between income and haemoglobin level was observed; this difference may have been due to a more leisurely life in the higher income groups.

The haemoglobin level of boys of town I was lower than that of the boys of any of the other towns, and that of grammar and public school boys in town L was slightly higher than for modern school boys in the same city. The reasons for these differences in boys living in different parts of England and in different surroundings are being further investigated.

ADDENDUM.—Since writing the above, the doctors of women with Hb below 80% have tried the effects of iron therapy, in almost every case with satisfactory results. The proportion (8.9%) of women with Hb below 80% in this unselected sample and their ready response to iron medication suggests that the work of the general practitioner would be facilitated by routine Hb determinations in women patients. The colour of the mucous membranes, as reported elsewhere (Adcock *et al.*, 1949) may fail as an index of Hb level, but the Tallqvist method provides a

simple and inexpensive means of ascertaining the Hb level with sufficient accuracy for practical purposes. This method was found by Macfarlane *et al.* (1948) to compare surprisingly well with other more complicated procedures.

EFFECT OF VITAMIN-K PREPARATIONS ON HYPOPROTHROMBINAEMIA INDUCED BY DICOUMAROL AND TROMEXAN

BY

A. S. DOUGLAS, M.B., B.Sc., M.R.C.P.
M.R.C.P.Ed., F.R.F.P.S.

Registrar, Royal Infirmary, Glasgow

AND

ALEXANDER BROWN, M.D., F.R.C.P.Ed.
F.R.F.P.S.

Senior Lecturer in Medicine, University of Glasgow;
Assistant Physician, Royal Infirmary, Glasgow

(From the University Department of Medicine, Royal Infirmary, Glasgow)

The administration of dicoumarol (3,3'-methylene-bis-(4-hydroxycoumarin)) or "tromexan" (bis-3,3'-(4-oxy-coumarinyl)-ethyl acetate) in the treatment of thromboembolic states may lead to severe or even fatal haemorrhage. Although careful control of treatment by repeated estimation of the blood prothrombin levels reduces this risk, a reliable and convenient antidote against such potent therapeutic substances would be of great value. Both dicoumarol and tromexan are anti-coagulants by virtue of their causing hypoprothrombinaemia, and the two measures recommended to reverse this effect are the administration of preparations possessing vitamin-K activity and the transfusion of blood. There is no doubt that the latter treatment gives immediate and significant results, but for it to be most effective the blood must be in sufficient quantity. It is not always easy to meet this requirement, and reliance may be placed on the use of vitamin-K preparations such as are commercially available.

There is a measure of belief, based on experimental observations carried out during the past ten years, that these vitamin-K preparations are capable of reversing dicoumarol-induced hypoprothrombinaemia. From the available evidence at hand there can be no doubt that substances with vitamin-K activity do possess such powers, but there is still much confusion regarding the practical value of the various preparations which are available for this purpose.

It is hoped that the experiments described below will provide more conclusive evidence concerning the action and therapeutic value of these preparations.

Material and Methods

Either dicoumarol or tromexan was administered in therapeutic doses to patients in whom there was no obvious potential source of haemorrhage or evidence of hepatic, alimentary, or renal dysfunction. A test dose of the anticoagulant drug was given, and the effect on the prothrombin levels was observed at least daily. When the prothrombin levels had returned to normal, and had remained normal for two to three days, the same dose of the same drug was repeated, and a selected dose of a vitamin-K preparation was given. Plasma prothrombin levels continued to be estimated at least daily. In a few instances the technique was varied in respect of time of administration and of the number of the doses of vitamin K. The variations are indicated with the results in Table II.

The hypoprothrombinaemia expected from the anticoagulant therapy was not usually beyond customary therapeutic levels, as it was not considered necessary or justifiable to induce dangerous depletion of the plasma prothrombin.

TABLE I.—Details of the Vitamin-K Preparations Tested

Substance	Other Designation	Route of Administration	Dosage
2-methyl-3-phytyl-1:4-naphthoquinone	Vitamin K ₁	Intravenously	200-340 mg. single doses
2-methyl-1:4-naphthoquinone	"Prokayvit" (B.D.H.); menaphthone; menadione	Intramuscularly	15-30 mg. in 2-3 days
2-methyl-1:4-naphthohydroquinone diacetate	Acetomenaphthone; oral prokayvit (B.D.H.)	Orally	90 mg. in 3 days
2-methyl-1:4-naphthohydroquinone carboxymethoxine	"Kapilon" (Glaxo)	Intramuscularly	60 mg. in 3 days
2-methyl-1:4-naphthohydroquinone diphosphate	"Synkavit" (Roche)	Intravenously	300-1,600 mg. in 3-4 days
Dipotassium 2-methyl-1:4-naphthylene bisulphate	Water-soluble K analogue (Boots)	"	200 mg. i.v. single dose

Vitamin-K Preparations.—The vitamin-K substances which were tested, and their routes of administration, are shown in Table I. With the exception of vitamin K₁ these preparations are readily available commercially, and the doses of those which were given parenterally were limited

only by the occurrence of untoward reactions. In the case of vitamin K₁, which is fat-soluble and which was received as an oily concentrate, a preparation suitable for intravenous administration was made as described by Davidson and MacDonald (1943). The oily fluid was dissolved in absolute alcohol (200 mg. K₁ in 4 ml. alcohol), and the solution was then added to 5% glucose (200-400 mg. K₁ in 500 ml.). The preparation was then autoclaved. Suspension of the vitamin in the glucose solution was assisted by injecting the alcoholic solution forcibly through a long fine needle into the centre of the bottle of glucose solution, but in spite of this the preparation tended to be unstable and had to be used almost at once. This preparation of vitamin K₁ was administered by intravenous infusion over a period of half to five hours without delay, otherwise the vitamin K₁ tended to settle out and adhere to the glass, with consequent loss of potency. No untoward reaction of any kind was encountered.

Estimation of Plasma Prothrombin.—Plasma prothrombin was estimated by the one-stage method of Quick. The same batch of rabbit-brain thromboplastin was used in each case, for the control and the test periods. The estimations were carried out on 100% and on 12.5% plasma. Only the figures obtained with 100% plasma are recorded here.

Results

The results of the various therapeutic trials of the vitamin-K analogues against the hypoprothrombinaemic effect of dicoumarol and tromexan are presented in Table II. In the case of vitamin K₁ the results of single tests are tabulated. In the case of the other preparations the average results from groups of patients are recorded: a more detailed analysis of these results is given below.

Vitamin K₁

Vitamin K₁ was tested against a single dose of tromexan in three patients. In the first case (Table II) 900 mg. of tromexan resulted in a prothrombin time approximately four times normal. The same dose of tromexan was given on the first day of the test period, and on the following day, when the prothrombin time had begun to rise, 200 mg. of vitamin K₁ was given intravenously. Within twenty-four hours the prothrombin time was 19 seconds, as compared with 60 seconds at this stage in the control period. In Case 2, 200 mg. of vitamin K₁ given at the same time as 900 mg. of tromexan appeared to act as a complete antidote. In Case 3

the effect of 900 mg. of tromexan was likewise blocked by simultaneous administration of 340 mg. of vitamin K₁. As an additional check on the method of testing, this patient was given a further dose of tromexan without vitamin K₁. Hypoprothrombinaemia resulted.

Vitamin K₁ was tested against a single dose of dicoumarol in two patients. In the first of these (Case 4) the administration of 200 mg. of vitamin K₁ on the third day of the test period was followed by return of the prothrombin time to pre-treatment levels within twenty-four hours. In Case 5 the simultaneous administration of 300 mg. of vitamin K₁ was almost completely effective in blocking the action of 400 mg. of dicoumarol.

As a further test of the action of vitamin K₁ (Case 6) 900 mg. of tromexan was given over two days. On the third day, when the prothrombin time was 40 seconds, 200 mg. of vitamin K₁ was given intravenously. The prothrombin time fell to 30 seconds in two hours, and to normal within twenty-four hours. Case 7 illustrates the effect of 300 mg. of vitamin K₁ on a persistently high prothrombin time (75 seconds) occurring in a patient who was given 300 mg. of tromexan daily for several weeks for therapeutic purposes. In spite of the administration of the usual daily dose of tromexan, vitamin K₁ produced a rapid fall in the prothrombin time to 21 seconds within six hours.

From these investigations it is evident that when 200–340 mg. of vitamin K₁ was given at the same time as a reasonable therapeutic dose of tromexan or dicoumarol the action of the anticoagulant drug on the plasma prothrombin levels was completely, or almost completely, inhibited. When the vitamin was given at any time after hypoprothrombinaemia had been induced, the prothrombin levels were restored to normal in 24 hours. Furthermore, significant reduction of the prothrombin time occurred within an even shorter period, and safe values were achieved within six to nine hours even when previously the hypoprothrombinaemia had been more severe than is usually considered necessary for therapeutic purposes.

Menaphthone and Acetomenaphthone

The average results of the intramuscular administration of menaphthone (Group 8, Table II) suggest that this substance had an incomplete inhibitory effect on mild hypoprothrombinaemia induced by tromexan. In this group the individual test results and the control results were practically identical.

Acetomenaphthone was given orally to seven patients, to five who had received tromexan, and to two who had received dicoumarol. The average figures for those given tromexan (Group 9) suggest that the response to the anticoagulant was modified slightly by the acetomenaphthone. The individual results indicated that the effect of this vitamin-K analogue was slight and inconstant. Acetomenaphthone was tested against dicoumarol in two patients (Group 10). In each the test curve and the control curve were identical. Although larger doses of menaphthone and acetomenaphthone might well have been given by mouth, it was felt that oral treatment was unsuited to this purpose and no further observations were made with acetomenaphthone. Dosage of menaphthone was limited by pain which followed the intramuscular injection.

Kapilon, Synkavit, and Water-soluble K Analogue (Boots)

Kapilon was tested against tromexan in five patients (Group 11, Table II). In no case could it be said that kapilon given intramuscularly in doses of 20 mg. daily for the first three days significantly affected the response to tromexan. Kapilon was tested against dicoumarol, which was given in doses of 300 mg. During the test period kapilon was given in doses of 20 mg. on the first and third days. In all three patients slight but significant modification of the prothrombin response occurred. In no case, however, did the prothrombin time return to normal within three days of administration of the first dose of kapilon.

Synkavit, given intravenously in doses of 100 mg., was tested against tromexan in six patients (Group 13). In five of these the control and the test curves were practically identical. In the sixth case of this group slight modification of the response occurred during the test period. Synkavit was tested against doses of dicoumarol, which produced prothrombin times of 30–40 seconds, in five patients (Group 14). Each patient was given 100 mg. of synkavit daily for the first three days of the test period, and in no case was there any demonstrable effect on the prothrombin-time curve. As an additional test of the action of synkavit, even larger doses were given (400 mg. intravenously), beginning on the day before the administration of tromexan (Group 15) and continuing for a further three days. No modification of the action of the tromexan was demonstrated: the control curve and the test curve were identical.

Water-soluble K analogue (Boots) was tested against tromexan in one patient. Given intravenously in a dose of 200 mg. it slightly modified the effect of the anticoagulant (Group 16) but failed to reduce the prothrombin time to normal within 24 hours.

The various water-soluble vitamin-K analogues have thus been shown to be relatively inactive against the hypoprothrombinaemic effect of tromexan and dicoumarol. Although in some instances—notably the tests of kapilon against dicoumarol—an effect was demonstrated, this effect was insufficient to prevent a fall in plasma prothrombin concentrations as a result of the administration of a single relatively small dose of the anticoagulant. That the lack of effect is not merely a matter of dosage of the vitamin-K analogue is indicated by the complete failure of 1,600 mg. of synkavit given over a period of four days to modify the normal therapeutic effect of a single dose of tromexan.

Discussion

Among all the vitamin-K analogues tested against dicoumarol and tromexan in this investigation the only substance which was uniformly significantly active was vitamin K₁. This material was given intravenously in doses of 200–340 mg., and it was almost invariably completely effective in blocking or in reversing the action of the anticoagulant under the circumstances of the test. The other substances tested did occasionally modify the effect of the anticoagulant, but the effect was inconstant and slight. Comparable doses were not always given, but, from the practical point of view, oral administration of vitamin K is unlikely to be satisfactory as an emergency treatment, and, given by other routes, the doses of menaphthone and synkavit were limited by local or general reactions.

In the present investigation no attempt was made to give doses of anticoagulants which would result in dangerously low prothrombin levels. It might therefore be considered that the tests do not give information directly applicable to the treatment of the hypoprothrombinaemic emergency. On the other hand, this would merely point to some doubt about the value of vitamin K₁ under more exacting conditions, and the immediate result of administering it to a patient with a prothrombin time (100% plasma) about four times normal (Case 7, Table II) without stopping the tromexan administration is good evidence of the potency of this substance even in very adverse conditions. As regards the other analogues, the relatively small dosage of the anticoagulant employed serves to emphasize the inefficiency of these vitamin-K preparations.

During the past 10 years considerable interest has been shown in the effect of vitamin-K analogues on dicoumarol-induced hypoprothrombinaemia, and numerous experiments have been carried out both in animals and in the human subject. It cannot be said, however, that there is general agreement about either the relative effects of the various vitamin-K preparations or the form of vitamin-K activity which is most suitable for the treatment of hypoprothrombinaemic bleeding occurring as the result of the administration of dicoumarol or tromexan.

This lack of agreement has probably been due to two variable factors. In some experimental trials water-soluble vitamin-K preparations were regarded as effective when the anticoagulant was given in minimum active quantities. There is good evidence that this is so (Shapiro *et al.*, 1943), but little that they are effective against therapeutic doses of dicoumarol. The second variable factor has been the expected response to administration of vitamin K. Many writers have considered adequate a response demonstrable in the course of days and have been content to advise the use of the water-soluble preparations. Our own findings on the inadequacy of these preparations and the greater reliability of vitamin K₁, together with evidence presented by others on the use of vitamin K₁ or its oxide, seem to justify the conclusion that there are only two known effective means of treating hypoprothrombinaemia induced by dicoumarol or tromexan. These are by transfusion of blood or by administration of vitamin K₁ or its oxide.

In view of the fact that transfusion, to be effective, involves the use of blood or of frozen fresh plasma from possibly more than a single donor, and that thereby delay may often occur in beginning adequate treatment, there is some justification for regarding a suitable preparation of vitamin K₁ or its oxide as an essential material in any department in which treatment by dicoumarol or tromexan is being carried out. Neither vitamin K₁ nor its oxide is available commercially, but it could doubtless be made so, and, as has been shown (Shoshkes *et al.*, 1950), a convenient, effective, and stable emulsion can be prepared for intravenous use. No reliance should be placed on the use of larger doses of the synthetic water-soluble vitamin-K analogues. The action of vitamin-K preparations against the hypoprothrombinaemic effect of dicoumarol or tromexan is not simply a matter of dosage. There is a difference in the action of water-soluble and oil-soluble preparations which has not so far been explained except that it has been related to the presence of the "phytyl" group in the molecule of vitamin K₁ (Miller *et al.*, 1950).

Summary and Conclusions

The effect of certain substances with vitamin-K activity in modifying the action of dicoumarol and tromexan has been investigated in the human subject. The vitamin-K preparations employed were vitamin K₁, menaphthone, acetomenaphthone, kapilon, synkavit, and water-soluble K analogue (Boots).

Apart from vitamin K₁, these substances have been shown to possess a minor and inconstant ability to modify the action of these anticoagulants. Vitamin K₁, on the other hand, is a reliable and efficient antidote, and is capable of completely blocking the action of therapeutic doses of dicoumarol and tromexan, and capable of restoring to safe levels within a few hours excessive hypoprothrombinaemia due to these drugs.

Since these differences between the vitamin-K preparations are not merely a question of dosage, of all the substances tested here only vitamin K₁ can be regarded as a reliable antidote for a hypoprothrombinaemic emergency.

We wish to thank Professor L. J. Davis for helpful advice, and Dr. F. Wrigley, of Roche Products, Ltd., for providing the vitamin K₁ used in this investigation. Part of the expenses of this work was defrayed by the Rankin Research Fund of the University of Glasgow.

ACQUIRED SENSITIVITY TO PARA-AMINOSALICYLIC ACID

BY

S. J. STEEL, M.D., M.R.C.P.

(From the Brompton Hospital, London)

Since the widespread use of *para*-aminosalicylic acid (P.A.S.), either by itself or in conjunction with streptomycin, in the treatment of pulmonary tuberculosis, reactions have occurred which indicate that it is possible to distinguish two groups of cases.

First there are those patients with a natural intolerance to P.A.S. who develop gastro-intestinal symptoms during the first few days of treatment. As reported by Lehmann (1947) nausea is the symptom most frequently encountered, and may be accompanied by vomiting and diarrhoea in cases which exhibit a greater intolerance to the drug. Nagley and Logg (1949) pointed out that these effects are often due to impurities in the preparation of the drug and are seldom so severe as to cause abandonment of P.A.S. therapy.

Secondly, there are a few patients who develop an acquired allergic sensitivity to P.A.S. In these cases the onset of symptoms is characteristically sudden and usually occurs between two and four weeks after the beginning of treatment. Drug fever, with a rise of body temperature to 100–103° F. (37.8–39.4° C.), and symptoms of a marked constitutional disturbance are the usual features of this type of reaction and are commonly accompanied by a pruritic skin eruption as reported by Kierland and Carr (1949). Other toxic effects which have been recorded include renal damage (Nagley and Logg, 1949), hepatitis and enlargement of lymphatic nodes (Cuthbert, 1950), and lowering of the serum potassium (Cayley, 1950).

Case Report

The following case of an unusually severe sensitivity reaction to P.A.S. recently occurred at the Brompton Hospital.

A draughtsman aged 29 was admitted with the following history. He had developed pulmonary tuberculosis involving the right lung in 1944, for which he was treated by rest for 10 months at the Royal National Sanatorium, Ventnor. During this time a right artificial pneumothorax was induced, but this was abandoned after two months owing to the formation of an effusion. He subsequently returned to work and remained well until January, 1951, when, following a febrile coryza, he had a sudden haemoptysis of about 1 oz. (28 ml.).

Treatment consisted of rest in bed at home, and in March he began treatment with P.A.S., 18 g. daily by mouth. Three weeks later he had an evening rise of temperature, followed in two days by nausea, vomiting, and headache, and four days later by a morbilliform rash and pyrexia rising to 104° F. (40° C.). P.A.S. was discontinued, and the pyrexia and rash subsided on treatment with mepyramine hydrogen maleate ("anthisan").

One week later, while still receiving mepyramine, 100 mg. thrice daily, he was given two 3-g. doses of P.A.S., and within six hours the temperature rose to 102° F. (38.9° C.) and the rash returned. Despite discontinuation of P.A.S. the pyrexia and rash persisted, and five days later there was tender enlargement of the cervical, axillary, post-occipital, inguinal, and epitrochlear lymphatic nodes accompanied by sore throat, epigastric pain, and tenderness. The following

day he was clinically jaundiced, with a tender liver enlarged to 1 in. (2.5 cm.) below the costal margin. The rash, which became confluent on the face and neck while remaining morbilliform on the trunk, was accompanied by severe pruritus. The spleen was not palpable.

Investigations.—Urine: No albumin; excess urobilinogen and a small amount of bilirubin present. Serum bilirubin 4.5 mg. per 100 ml. Direct positive Van den Bergh reaction. Paul-Bunnell test, negative without absorption. Wassermann reaction and Kahn tests, negative. A blood count showed: Hb, 73%; red cells, 4,100,000; C.I., 0.9; white cells, 14,300 per c.mm. (polymorphs 34%, lymphocytes 48%, monocytes 2%, eosinophils 15%, basophils 1%).

Treatment was changed to diphenhydramine hydrochloride ("benadryl"), 50 mg. four times daily, and he responded with slow but steady improvement. Calamine lotion successfully relieved the pruritus. Within 10 days the temperature fell by lysis, the glands mostly subsided, clinical jaundice disappeared, and the liver became normal in size and no longer tender.

During the first week of treatment with benadryl the rash faded, pruritus ceased, and desquamation began on the face and neck, followed by desquamation on the trunk during the second week and on the arms and legs during the third week. Some glandular enlargement of the inguinal and axillary groups persisted until the desquamation on the limbs was complete.

By the end of the third week the serum bilirubin was 1.3 mg. per 100 ml., and the white blood cells numbered 16,400 per c.mm., but the lymphocytosis had subsided and the eosinophilia showed a decrease (polymorphs 60%, lymphocytes 20%, monocytes 10%, eosinophils 8%, basophils 2%).

Patch Tests.—At the conclusion of treatment, when clinically no manifestation of the sensitivity reaction remained, patch tests were performed (see Table). Two cases were selected as controls. Control 1 was a patient who had never received P.A.S. Control 2 was a patient receiving P.A.S., 18 g. daily, who had shown no manifestations of sensitivity.

Patch Tests

Test	Patient Before Desensitization	Patient After Desensitization	Control 1	Control 2
Aqueous solution of P.A.S. 5% ..	++	0	0	0
Chloroform ..	0	0	0	0
Aniline ..	++	+	0	0
Para-aminobenzoic acid ..	+	0	0	0
P.A.S. 5% solution in chloroform ..	+++	0	0	0
Meta-aminophenol ..	++	0	0	0
Benzoic acid ..	0	0	0	0
Salicylic acid ..	+	0	0	0

For these tests P.A.S. was prepared as a 5% solution and the other reagents as equimolecular solutions in chloroform.

Desensitization.—The patient was successfully desensitized by giving graduated doses of P.A.S. by mouth. A single dose of 50 mg. was given on the first day, and this was increased by 50 mg. each day in divided doses. If pyrexia occurred the dose was halved the following day and then increased as before from the reduced level. When the daily dose of P.A.S. reached 1 g. it was increased by 0.5 g. each day until a satisfactory therapeutic dosage of 15 g. daily was obtained. After desensitization the patch tests (see Table) were repeated; they proved negative with the exception of a doubtful positive reaction to aniline.

Discussion

Patients who show intolerance to P.A.S. or associated impurities should be distinguished from those who develop an allergic sensitivity by the differences described above

in the mode of onset and severity of the reaction. Early recognition is important, because P.A.S. therapy may be continued safely despite mild gastro-intestinal symptoms, but should be withdrawn immediately if an allergic sensitivity develops, as otherwise it may be practically impossible to control the reaction.

Antihistamine drugs are generally found useful in the treatment of the sensitivity reaction once P.A.S. has been withdrawn, but, as Horne (1949) observed, they are insufficient to control it if P.A.S. therapy is resumed before the patient has been desensitized. Once sensitivity has developed, even a small dose of P.A.S. is enough to provoke a severe reaction. Madigan *et al.* (1950) reported this effect after a dose as small as 0.5 g. In the case reported above two 3-g. doses of P.A.S. were given after the patient had become sensitized, and, despite an adequate dosage of an antihistamine drug being maintained, a reaction of considerable severity occurred.

In sensitized patients, skin tests usually show a positive reaction to dilutions of P.A.S. of 5% and upwards and to dilutions of meta-aminophenol of 1% and upwards, as observed by Climie (1950). Positive results are still obtained with patch tests even after the clinical termination of a sensitivity reaction. After desensitization, however, patch tests become negative in most cases, although Climie reported a persistent reaction to meta-aminophenol.

The method of performing skin tests may influence the results obtained. The technique used in the cases reported here consists in applying to the skin a measured quantity of the reagent in solution in chloroform by means of a pipette and drying it in a current of air. The area is then covered with adhesive plaster, which is removed after 24 hours, and readings are made at 48 hours. This method has been found to give accurate results, and is relatively simple to carry out.

Patients who have developed sensitivity may be desensitized by giving small quantities of P.A.S. by mouth and gradually increasing the dose. A scheme beginning with 0.1 g. of P.A.S. daily was suggested by Madigan *et al.* (1950); this will improve the tolerance of the patient by slow stages until an effective daily dosage of P.A.S. is reached. In desensitizing the case reported above it was considered advisable, in view of the severity of the reaction, to use a modified method beginning with 50 mg. daily, and to increase the dose of P.A.S. more gradually up to the required therapeutic level of 15 g. daily.

Summary

A severe case of P.A.S. sensitivity is described. The manifestations were pyrexia, sore throat, pruritus, morbilliform rash, generalized glandular enlargement, jaundice, hepatomegaly, and epigastric pain, accompanied by a marked lymphocytosis and eosinophilia.

The response to antihistamine drugs and to desensitization is recorded.

Skin tests with P.A.S. and certain related chemical compounds were positive, but became negative after successful desensitization. The technique used for these tests is described.

I wish to thank Dr. A. B. Hill for his help with the reagents for the patch tests, and Dr. F. H. Young and Dr. J. G. Scadding for their valuable advice in preparing this article.

RELATION BETWEEN SENSITIVITY TO THIOPENTONE, SULPHONAMIDES, AND SUNLIGHT

BY

FRANKIS EVANS, M.B., F.F.A.R.C.S., D.A.
Anaesthetist, St. Bartholomew's Hospital, London

AND

JONATHAN GOULD, M.B., M.R.C.P., D.P.M.
*Associate Chief Assistant, Department of Psychological
Medicine, St. Bartholomew's Hospital, London*

Intravenous injection of thiopentone is a very frequent and, in experienced hands, safe procedure in both anaesthetic and narcoanalytical practice. Sensitivity reactions occur infrequently, Davidson (1943) mentioning two instances in 9,000 injections. We have administered over 15,000 injections in surgical and psychiatric practice and have encountered the three cases of sensitivity reported here. Two of these involved not the scarlatiniform rash commonly seen in these uncommon cases but angioneurotic oedema, and the other showed a less developed form of the syndrome. We wish to call attention to these uncommon reactions, which could, if unprepared for and unexpected, lead to grave difficulties, especially when encountered in the consulting-room as opposed to the operating theatre. We also wish to correlate our findings with other apparently relevant evidence concerning sensitivity to sulphonamide compounds encountered therapeutically.

Case 1

A single woman aged 26 had received 15 injections of thiopentone (0.15–0.35 g.) over a period of six months from January, 1948, in the narcoanalytical treatment of the depressively coloured anxiety state associated with very severe insomnia, from which she had suffered for five years. Response to treatment had been satisfactory. Injection of thiopentone caused sleep for three to seven minutes followed by a prolonged drowsiness, without signs of sensitivity. In April, 1950, a further narcoanalytical session was occasioned by a recurrence of symptoms, and subjective relief was obtained. In May she again presented herself for narcoanalytical treatment. The day had been very sunny, but naturally she did not mention the fact that she had exposed her face and arms for 20 minutes at 3 p.m., two hours before the injection (during which no perivenous leakage occurred) of 0.35 g. of thiopentone.

Five minutes after the end of the injection, as she was rousing from the deepest sleep, her face became brilliantly red and minor restless movements of the head and neck occurred. Restlessness increased and within three to five minutes the forearms and elbow regions were reddened, the patient clasping the lower abdomen. Marked urticaria appeared above the elbows, and colic and numbness of the lips were complained of in a hoarse voice. Her face and eyelids were swollen, and pitting oedema was present over the radius. Twelve minutes after the injection the pulse was thin and thready, the rate being 146. A diagnosis of angioneurotic oedema was made, and adrenaline, 7 min. (0.4 ml.), was given subcutaneously at the rate of 1 min. (0.06 ml.) a minute with no good effect. At this stage the eyelids were beginning to evert and the eyes were completely closed. The lips and the tongue were swollen, and tenderness and pain were felt in the throat as well as in the abdomen; but breathing was not embarrassed, and cyanosis was absent.

One tablet of mepyramine hydrogen maleate ("anthisan") was taken with difficulty. Calcium gluconate, 10 ml. of 10% solution, was injected into the vein at the rate of 1 ml.

a minute. By the time that 6 ml. had been administered subjective relief was noticed and erythema was subsiding. As the distribution of the skin reaction was so reminiscent of sulphonamide sun-sensitivity, the patient was asked at this point whether she had been sitting in the sun earlier in the day. A hoarse affirmative answer was obtained. Abdominal cramps persisted for a further 10–15 minutes. The blood pressure was 136/78 at the end of the injection of calcium gluconate, the pulse having fallen steadily from 156 to 110 during the time of the injection. She then began to feel cold and started to shiver, but this passed off in about ten minutes. One and a half hours after the injection of thiopentone she had recovered, apart from feeling rather shaken, drowsy, and muddle-headed.

Case 2

A woman aged 60 suddenly developed haematuria (due to papilloma of the bladder) associated with transient oedema of the lip while on holiday in Canada. After her return to England and during the succeeding four or five years she was at intervals submitted to intravenous anaesthesia on seven occasions, for purposes of cystoscopy and diathermic cautery of the papilloma. Premedication on the first three occasions was with "omnupon," 1/3 gr. (22 mg.), and scopolamine, 1/150 gr. (0.43 mg.). Hexobarbitone ("evipan") was used for the first two operations with no untoward sequelae. Thiopentone, 0.5 g., was used on the third occasion, its initial exhibition being followed by a red papilliform rash of the thorax and neck, and erythema of the face. Post-anaesthetic itching occurred. Some months later a second injection of thiopentone was followed by a similar reaction, with, in addition, transient mild angioneurotic oedema of the lips, which subsided spontaneously. Hexobarbitone was again used uneventfully for the fifth anaesthetic, but on the sixth occasion, in the absence of hexobarbitone, a different brand of thiopentone was used. Again the cutaneous reaction, with angioneurotic oedema, was elicited, and was well controlled by antihistaminics by mouth. On the seventh and most recent occasion hexobarbitone was given and the patient recovered uneventfully.

Case 3

A married woman aged 33, suffering from obsessional neurosis with anxiety hysteria, uneventfully received thiopentone, 0.25–0.35 g., intravenously on more than 40 occasions (at weekly intervals), reacting with sleep of one to three minutes, followed by drowsiness. After an interruption of treatment for six weeks, cough and laryngeal tickling appeared during the recovery of consciousness, and were at first thought to be due to an incipient cold which was later associated with nasal catarrh. Recovery from thiopentone, however, continued to be associated with cough and laryngeal discomfort after the infection had passed, and in a few weeks there occurred a red blotchy condition of the face and neck which persisted for 20 minutes or so. Systemic disturbances and itching were absent. Substitution of a sulphur-free intravenous barbiturate ("cyclonal sodium" brand of hexobarbitone) in place of thiopentone in equivalent dosage (0.6–0.8 g.) was followed by uneventful recovery from the induced sleep.

Comment.—These three cases illustrate sensitivity to thiopentone, and Cases 2 and 3 suggest very strongly that the sulphone radical is involved. Case 1 is, we believe, the first recorded instance of photosensitivity to thiopentone. It was, in fact, this case which prompted a search of the literature for similar cases, and led to a review of sensitivity to barbiturates and photosensitivity to sulphonamides.

Literature and Discussion

Barbiturate sensitivity, though uncommon, may manifest itself somatically (when it usually takes the form of a maculo-papular rash, possibly associated with systemic disturbance and pyrexia) and/or psychically (as excitement,

delirium, or collapse). The literature on angioneurotic oedema after barbiturates is small and scattered. Hunter (1943) briefly describes urticaria after incision of a septic finger under thiopentone, and mentions angioneurotic oedema after hexobarbitone, quoting Hewer (1939) in support. 'We found reference in Hewer only to angioneurotic oedema after pentobarbitone, which is of interest in view of Case 2. Hunter's main case is of idiosyncratic systemic reaction to thiopentone in an R.A.F. officer who had previously reacted normally to inhalation anaesthesia. From his description, the lesions appear to be restricted to the areas exposed to the sun (cf. sulphonamide sensitivity and Case 1). In Davidson's (1943) two cases the sensitivity consisted of scarlatiniform rashes, with transient pyrexia.

Knauss (1946) describes urticaria following dental extraction under thiopentone in a man aged 41 who had, a month earlier, uneventfully undergone the same procedure but with a preliminary local injection of adrenaline. Peterkin (1946) describes the occurrence of purpuric reactions of the trunk following thiopentone anaesthesia on three occasions in a man who had previously and uneventfully received inhalation anaesthesia. Following this, Warren (1946), R. H. Moore (1946), and P. H. Moore (1946) each described a case. In all three cases urticaria developed—in one instance after hysterectomy in a tuberculous patient, and in another in a man (who had 40 times uneventfully received thiopentone with or without inhalation anaesthesia in connexion with a perineal wound) when he was given 1 g. of thiopentone. In this case a subsequent administration of 0.5 g. of thiopentone combined with inhalation anaesthesia passed off uneventfully. Apart from these six cases mentioned in the literature, Lundy (1942) makes passing mention of the occurrence of urticarial reaction in thiopentone anaesthesia.

While it is recognized that barbiturates produce skin-sensitivity reactions, photosensitivity seems much less common. Stryker (1939) describes the case of a child aged 2 who developed an exfoliative dermatitis after receiving barbiturate for six weeks. Four months later the child developed an acute dermatitis of the exposed areas after playing in the sun, and was found to be excreting barbitone and porphyrins in the urine. Stryker quotes Schulzberger as considering barbiturates capable of giving rise to photosensitivity.

A local vesicular eruption (possibly generalized and exfoliative) is the commonest form of skin-sensitivity reaction to sulphonamides, and is most readily evoked by repeated topical application. Urticarial photosensitivity was noticed in Middle East troops, and Peterkin (1945) found 72% of 500 cases of sulphonamide dermatitis to be photosensitive. Watkinson and Hillis (1947) discuss the relationship between oral sulphonamides, sunlight, and the pustulation stage of vaccinal lesions in R.A.F. personnel. They found the highest incidence of sulphonamide photosensitivity associated with the pustulation stage of the lesion. Where vaccination did not take, or was refused, photosensitivity did not occur, even though exposure to sunlight and ingestion of sulphonamides were the same in all troops. They support Erskine's theory that toxins liberated from a buried focus are causative of photosensitivity.

Park and Platts (1942) described photosensitivity in 3.4% of (mainly ambulant) men exposed to strong sun and receiving oral sulphonamides. In a case of acute tonsillitis an unusually severe skin rash developed on the first day of oral sulphonamide (as opposed to the usual 8th–10th day), the rash being concentrated in the areas exposed to the sun, even though the last exposure had been three days earlier. They regard this case as having "photo-allergy" (Epstein, 1939), although Epstein's criteria are apparently not fulfilled. (These are solar reaction without oedema preceding injection of sulphonamide, and followed in ten days by spontaneous development of oedema at the site of injection, or elsewhere, or an earlier oedematous reaction in response to solar irradiation, provided that a certain "critical" amount of sulphonamide has been injected.)

Porphyrin excretion has not been fully investigated in the current literature (owing to circumstances), although the significance of coproporphyrin I as a photosensitizer is well recognized. Its presence in the excreta of patients taking sulphonamides was pointed out by Rimington and Hemmings (1938), who also mention that sulphonamide may evoke photosensitivity and promote the excretion of coproporphyrin I. They compare the clinical pictures of acute porphyrinuria and sulphonamide intoxication. The present paper may indicate the connexion between sulphonamides and thiobarbiturates with regard to sensitivity reactions.

Burckhardt (1948) has shown that burning, tanning, and specific photosensitivity provocation occur independently of each other at different light wavelengths, and that photosensitive reactions occur only in the areas actually irradiated by the provocative wave-band. Local tissue damage and, in some cases, systemic effects analogous to toxic reactions are characteristic of sunburn, and are in keeping with the presence in the circulation of a substance derived from tissue damage (? histamine-like, ? porphyrin-like). Systemic reactions generally last less than three days, and pigmentation usually begins after this time. Skin repeatedly exposed to ultra-violet radiation is less likely to burn even in the absence of pigmentation.

Correlating these observations, we put forward the hypothesis that skin-sensitivity reactions here considered depend upon the interaction of the following factors. (1) Tissue damage, as septic focus, mechanical trauma, local infection, or interference with tissue metabolism—for example, by drugs. (2) The presence of the sulphone radical, either as thiobarbiturate or as sulphonamide, locally applied or given by mouth or injection. Depending on the intensity of these two factors, local or general reactions may result. (3) Sunlight may act as a form of factor 1 when the burning effect is marked, and hence may be sufficient with factor 2 to produce a non-photosensitivity reaction. The longer rays may also, acting with factor 1 and/or factor 2, trigger off a true photosensitivity reaction. These reactions occur when a critical level (Epstein) is overstepped. The double role of sunlight seems to resolve the discord mentioned by Urbach and Gotlieb (1946) concerning skin colour and sulphonamide photosensitivity, on the basis of acclimatization to the burning rays of the sun as opposed to the tanning rays.

The case (Park and Platts, 1942) of tonsillitis shows the synergism of local tissue damage and circulating products from the throat, and in this instance the rash is described as photosensitive. From Park and Platts and from Watkinson and Hillis it is clear that skin areas not submitted to solar exposure or to mechanical trauma—for example, the bathing-drawers area—are never involved in sulphonamide photosensitivity, whereas the ischial tuberosities of bedridden patients are more susceptible than those of ambulant cases. In Case 1, a patient who burned easily in the sun, recent exposure had occurred, and presumably breakdown products were circulating. This would account for the local and general symptoms, on the hypothesis advanced above. Similarly, in Case 2 the focus of tissue damage was a necrosing papilloma of the bladder.

Clark (1943) describes a case, clearly illustrative of the interaction of local and general factors, in which the sequence was as follows: first four days, successful local treatment of skin lesion with sulphonamide in strong sun; ten days later sulphathiazole by mouth precipitated an acute reaction in the areas exposed to the sun, followed by secondary infection, for which seven days later he was given sulphadiazine by mouth, provoking a generalized scarlatiniform rash; six weeks later, after recovery, local sulphathiazole provoked a local reaction, and on the following day oral sulphathiazole provoked a reaction in the sun-exposed areas; ten weeks later local application of sulphathiazole provoked a local reaction.

It is perhaps relevant to point out here that in surgical practice thiopentone is usually given if established tissue damage exists and hence tissue-breakdown factors are

circulating. This would account for the tendency to the generalized form of sensitivity reaction. All the cases from the literature cited in this paper showed significant tissue damage related to general reactions.

TERRAMYCIN IN INFECTIONS IN INFANTS AND CHILDREN

BY

B. WOLMAN, M.D., M.R.C.P., D.C.H.

AND

A. HOLZEL, M.D., D.C.H.

(From the Department of Child Health, University of Manchester)

"Terramycin" is a new antibiotic obtained from *Streptomyces rimosus*, an actinomycete isolated from the soil (Finlay *et al.*, 1950). Its physical and chemical properties have been studied by Regnà and Solomons (1950), and it has been shown to be a stable, amphoteric substance of high potency (Linsell and Fletcher, 1950). Preliminary experimental studies (Hobby *et al.*, 1950) have shown that it is active both *in vitro* and *in vivo* against a wide variety of pathogenic organisms. It is effective against Gram-positive and Gram-negative bacteria, spirochaetes, rickettsiae, and certain of the larger viruses, yet is distinguished by its low toxicity (Finlay *et al.*, 1950; King *et al.*, 1950; Herrell *et al.*, 1950).

Terramycin is supplied in 50, 100, and 250-mg. capsules of the crystalline hydrochloride salt, and as a yellow crystalline powder which dissolves easily in a specially prepared cherry-mint-flavoured liquid to make an elixir ("terrabor") suitable for administration to infants and children. A special solution containing 25 mg. of terramycin as the crystalline hydrochloride, made up with 62.5 mg. of sodium chloride and 25 mg. of sodium borate, dissolved in 5 ml. of distilled water, is available for ophthalmic use.

This report is based on a study of the use of terramycin in various infections of infancy and early childhood. Sixty-six children were treated with this drug, no other therapy being given during its administration. The dosage was 50 mg. per lb. (450 g.) of body weight per day, the elixir being given by mouth at six-hourly intervals for a period of seven days to each of 54 patients. It was found to be extremely palatable, and no difficulties were encountered in its administration. In fact, ward sisters preferred its use to other antibiotics because it was taken so readily by infants and children. Routine white-cell estimations during the course of treatment did not show any depressant action on the total

count or on the polymorphonuclear elements. The special ophthalmic solution was used for the treatment of 12 newborn babies, and was instilled into the eyes in the following manner: one drop every minute for five minutes, followed by one drop every two minutes for ten minutes, the whole procedure being repeated three times a day.

Terramycin was used for the treatment of pneumonia (35 cases), upper respiratory tract infections (10 cases), tonsillitis (6 cases), pyuria (3 cases), and purulent conjunctivitis (12 cases).

Pneumonia

The 35 cases of pneumonia, all confirmed radiologically, showed the following age distribution:

0-5 months	..	..	6 cases	2 years	..	..	6 cases
6-11 "	..	..	7 "	3 "	..	..	5 "
1 year	..	..	11 "				

Nasopharyngeal swabs were cultured in every case, the predominating organism being shown in Table I.

TABLE I.—Predominating Organism on Culture of Nasopharyngeal Swab

Organism	No. of Cases
<i>Streptococcus viridans</i>	7
<i>Streptococcus haemolyticus</i>	5
Pneumococci	6
<i>Staphylococcus pyogenes</i>	2
<i>Haemophilus influenzae</i>	1
Friedländer's bacillus	1
Normal flora—no predominating organisms ..	13

In 23 cases the temperature fell to normal within 24 hours, in seven cases fever disappeared in 48 hours, and in one case in 72 hours. Improvement in appetite, colour, and general condition coincided with the settling of the temperature. Radiological clearing of the lungs usually took a few days longer than the disappearance of clinical signs.

One child, aged 3½ years, with a right lower lobe pneumonia, presenting characteristic clinical and radiological findings, showed no response to treatment until the dose was doubled and 100 mg. per lb. (450 g.) body weight per day was given. In this case the defervescence occurred by lysis over a period of eight days. No response to the drug was obtained in three patients (Table II), one of whom died.

TABLE II.—Details of Three Cases Not Responding to Terramycin

Case No.	Sex	Age	Dose	Diagnosis	Nasoph. Swab	Result
1	F	5/12	125 mg. 6-hrly for 7 days	R.L.L. pneumonia	<i>Staph. pyogenes</i>	Responded to "aureomycin"
2	F	3 yr.	250 mg. 6-hrly for 7 days	Broncho-pneumonia (coeliac disease)	Pneumococci	" "
3	M	6/52	100 mg. 6-hrly for 7 days	Broncho-pneumonia	Friedländer's bacilli; pneumococci; <i>Str. haemolyticus</i>	Death. Necropsy showed collapse of left lower lobe, consolidation of right middle and lower lobes with abscesses. Pus: Friedländer

Upper Respiratory Tract Infections

Ten children with upper respiratory tract infections, classified as rhinopharyngitis, laryngitis, and otitis media, responded similarly to those in the pneumonia group, with an improvement in the clinical condition and a return of temperature to normal in 24 hours. In one child with otitis media, the discharge from the ear ceased within 24 hours, but the other ear then suppurated. Both ears were completely dry within five days of the onset of therapy.

Tonsillitis.—Six children with tonsillitis improved within 24 to 48 hours of treatment.

Pyuria

Three children with pyuria were treated. One, aged 8 weeks, with a staphylococcal perinephric abscess, had improved after surgical drainage and penicillin therapy. Three weeks later, however, he developed an acute febrile illness due to a *Bact. coli* pyuria. Sulphonamide therapy produced a temporary improvement, but during the subsequent five months he showed two further episodes of urinary infection, each controlled by sulphonamides and streptomycin. A further recrudescence at the age of 8 months, due to a coliform infection superimposed on a non-functioning left kidney, was treated with terramycin, and after seven days' treatment the urine showed no pus on microscopy or organisms on culture. During a follow-up period of four months he has had no recurrence of pyuria.

The second patient, aged 2 years 10 months, had suffered for two years from recurring bouts of pyuria associated with a left megaloureter. Sulphonamides, streptomycin, and chloramphenicol in turn had produced only temporary improvement. Terramycin therapy has so far maintained the urine bacteria-free for the longest period to date, about six months.

The third patient, aged 2 years, developed recurrent attacks of pyelitis associated with a congenital abnormality of the left kidney. The infecting organism, *Bact. coli*, responded at first to streptomycin, but became resistant after one course of therapy. Three further episodes of pyuria cleared up quickly with terramycin, but improvement was maintained for short periods only. The organism, however, is still sensitive to this antibiotic.

Conjunctivitis

Twelve newborn babies with purulent conjunctivitis were treated with terramycin. Swabs of the purulent material were cultured. In each case a coagulase-positive *Staphylococcus aureus* was grown, and its sensitivity to penicillin, streptomycin, and terramycin determined. Six out of seven cases classified as mild, three classified as moderate, and two severe cases improved within 48 hours, as shown by cessation of discharge and disappearance of injection of the conjunctivae. Although many of the mild cases of conjunctivitis will clear up without antibiotic therapy, terramycin is useful in those cases requiring antibiotics but in which the organism has become resistant to penicillin and/or streptomycin. No evidence of clinical irritation due to the drug was noted.

TABLE III.—Cases of Conjunctivitis

Case No.	Type	Organism	Sensitivity			Results
			Penicillin	Streptomycin	Terramycin	
1	Mild	Coag.-pos. <i>Staph. aureus</i>	Resistant	Sensitive	Sensitive	Improved
2	"	"	Sensitive	"	"	"
3	"	"	"	"	"	"
4	"	"	Resistant	"	"	"
5	"	"	"	"	"	"
6	"	"	Sensitive	"	"	"
7	"	"	Resistant	"	"	"
8	Moderate	"	Sensitive	"	"	Improved
9	"	"	"	"	"	"
10	"	"	Resistant	Resistant	"	"
11	Severe	Coag.-pos. <i>Staph. A. Str. viridans</i>	Sensitive	"	"	"
12	"	Coag.-pos. <i>Staph. aureus</i>	Resistant	"	"	"

* Did not improve on terramycin. Responded to streptomycin.

Discussion

The broad antimicrobial spectrum of terramycin, combined with its low toxicity, ease of administration, and rapid absorption from the gastro-intestinal tract, suggests that this new drug is a most useful addition to chemotherapy.

In contradistinction to penicillin and streptomycin, which have to be given by injection, and to aureomycin and chloramphenicol, which, although given by mouth, are distinctly unpalatable, terramycin can be given in a pleasant form by the oral route. It is therefore particularly valuable in paediatric practice. Although a large number of reports on its use have already appeared in the American literature, opportunity of using the drug in this country has so far been limited, and no account of its value against the common infections of infancy and childhood has yet appeared.

Friedländer's bacillus is highly sensitive to the action of terramycin *in vitro* (Gunnison *et al.*, 1950), but so far no report describing its clinical effects in this type of infection has come to our attention. Hobby (1950, personal communication) mentioned three of five adult patients who showed complete resolution of lung consolidation within five days of the beginning of therapy. In our series, one infant with a Friedländer bronchopneumonia died.

Wooding and Scott (1951) reported the successful use of terramycin in 10 cases of bacterial pneumonia in infants and children, while Graves and Ball (1951), comparing the action of aureomycin, chloramphenicol, and terramycin in a series of 143 children with atypical pneumonia, considered terramycin to be the drug of choice in the treatment of this disease.

Two patients developed a scarlatiniform rash mainly involving the trunk and accompanied by a slight rise of temperature on the third day after cessation of treatment. As no other drugs had been given, it is assumed that this was a drug rash due to terramycin. Vomiting, diarrhoea, glossitis, and moniliasis were not seen. The "ano-rectal syndrome" described by Willcox (1951) in male adults treated for gonorrhoea was not noted.

Summary and Conclusions

A group of 66 infants and children with various infections were treated with terramycin, using a dose of 50 mg. per lb. (450 g.) body weight per day. Thirty-four out of 35 patients with pneumonia responded rapidly to treatment, in most cases within 24 hours. One patient with a Friedländer's bacillus pneumonia died.

Ten patients with upper respiratory tract infections, six with tonsillitis, and three with pyuria also showed a rapid and dramatic response. Eleven out of 12 infants with purulent conjunctivitis responded rapidly to the drug.

There were no toxic reactions, and it is stressed that terramycin, because of its wide spectrum of antibacterial activity and, in the form of the elixir, its easy and palatable administration, is particularly valuable in paediatric practice.

Grateful acknowledgments are due to Dr. Gladys L. Hobby, of Messrs. Charles Pfizer and Co. Inc., Brooklyn, New York, for generous supplies of terramycin, and to the physicians at the Duchess of York Hospital for Babies, Manchester, for permission to treat patients under their care. We wish to thank Professor Wilfrid Gaisford for advice in the preparation of this paper.

Medical Memoranda

Addison's Disease and Pregnancy

Pregnancy in patients with Addison's disease is unusual, and before the introduction of "eucortone" and "doca" it was almost invariably fatal (Perkins, 1932). More recently cases successfully managed through pregnancy have been described (Thorn *et al.*, 1941, 1942; Sheldon, 1945; Zwanenberg, 1945; Simpson, 1946; Knowlton *et al.*, 1949). Crises may occur in the early stages due to vomiting, but, once these have passed, the patients usually remain well until after delivery. In the first few days of the puerperium, however, crises of acute adrenal insufficiency are frequent. Hypoglycaemia may also be a serious complication, and irreversible coma may occur. Knowlton *et al.* (1949) recommend stabilization throughout the pregnancy with daily injections of intramuscular doca to allow for requirements which vary in the different stages. Little extra salt is advised, to give a wider margin of safety should vomiting occur and salt ingestion be discontinued. After delivery, intravenous glucose saline, 1 to 2 litres, and additional eucortone, 20 to 40 ml., are given daily.

CASE REPORT

A woman aged 35 was diagnosed as a case of Addison's disease in 1945. The diagnosis was based on the presence of typical pigmentation, including generalized brown discoloration of the whole skin, slaty-coloured patches in her mouth, a deep brown areola around each nipple, and pigmentation of scars. Her blood pressure at this time was 100/68 mm. Hg, and she was complaining of tiredness and of attacks of vomiting. A Kepler test was not performed, but serum sodium and potassium levels were estimated at times when she was thought to show signs of increasing adrenal insufficiency, and in 1949 these showed levels of 215 mg. and 32 mg. per 100 ml., respectively. She was maintained on implants of doca, 200 mg. being inserted every three to six months as she became deficient.

She was maintained in fairly good health until December, 1949. Then, in spite of an implant of 200 mg. on November 12, she noticed increasing weakness and vomiting. At the beginning of January, 1950, she was thought to be pregnant, because of amenorrhoea since November 4, and was admitted to hospital because of severe vomiting. In spite of her dehydration, a rapid pulse, and a blood pressure of 70/40 mm. Hg, her urine contained 14 g. of salt per litre (measured by Fantus's method). Intravenous saline was given, her daily salt intake was increased to 15 g. a day, and eucortone, 20 ml. daily, was given for three days.

After discharge from hospital in January she felt tired and unwell, and vomiting continued to be troublesome. The doca was therefore supplemented by intramuscular injections of an oily solution of doca, 5 mg. twice a week. At the 14th week of her pregnancy there was slight blood loss per vaginam, and she was thought to have a threatened miscarriage. This was treated by rest in bed, and at the same time she was stabilized on a daily maintenance dose of doca intramuscularly. This was increased to 10 mg. a day gradually, and her salt was reduced to 3 g. a day, her blood pressure remaining about 105/70. After discharge from hospital she was maintained fairly well on twice-weekly injections of 30 mg. of doca.

On June 8, she was admitted to hospital because of abdominal pains. From the size of the fundus twins had been suspected, and their presence was confirmed radiologically. On June 9 spontaneous delivery of male twins occurred. Delivery was premature at the 34th week, the infants being very underweight. One, weighing 2 lb. 12 oz. (1.2 kg.) at birth, has survived, the other died of asphyxia.

After delivery a 5% glucose saline drip was set up, 2 to 3 litres being given daily for four days. Doca intramuscu-

larly, 10 mg. a day, was continued, and supplementary eucortone to guard against a crisis. The blood pressure, however, was well maintained at a higher level than before delivery, and on the fourth day signs of electrolyte and fluid retention occurred, with the development of a lumbar pad. Eucortone and salt were therefore discontinued and doca was stopped for 24 hours. She was re-stabilized on doca, and was found to need 5 mg. a day. On July 19 400 mg. of doca was implanted in the erector spini muscles. Lactation began after delivery, but was rapidly inhibited by oestrogen.

Since delivery the mother and the surviving infant have remained well. The patient has, however, had three mild hypoglycaemic attacks, with faintness associated with hunger; each occurred while she was working before dinner. An oral glucose-tolerance test showed a normal curve, but an intravenous glucose-tolerance test showed marked hypoglycaemia three hours after the injection. She has been taking more frequent small carbohydrate meals since this time, and has been free from attacks for three months.

Comment.—Thorn *et al.* (1940) have shown that most patients with hypoglycaemic symptoms have a normal oral glucose-tolerance curve. Many, however, react abnormally to an intravenous glucose-tolerance test in which 0.5 g. of glucose per kg. is given during half an hour; hypoglycaemia develops three to four hours later.

I wish to thank Dr. D. H. G. MacQuaide for his assistance in preparing this paper and also Mr. G. Sturtridge, who undertook the obstetric management of the patient.

A Case of Interstitial Tubal Pregnancy

Individual cases of interstitial pregnancy are of sufficient interest and rarity to deserve attention. When such a case is associated with symptoms and signs even more puzzling than usual, it serves to re-emphasize the difficulty in diagnosis; when, in addition, a study of the case reveals an almost astonishing recurrence of ectopic implantation the details would appear to merit publication.

All writers agree on the rarity of the condition. Bethel Solomons (1949) described a case, the third in his own experience, and quotes Grusetz and Polayes (1944), who collected a total of 199 cases from the literature up to the year 1943. Wynne, in 1918, collected 1,547 cases of ectopic pregnancy and found that there were 18 cases of the interstitial variety, an incidence of 1.16%. MacFarlane and Sparling (1946) found seven cases in a series of 106. MacVine and Lees (1949) stated that at least two of the more severe forms of ectopic pregnancy were interstitial in a series of 107 cases extending over a 10-year period. Thus the incidence would appear to be in the region of 1% to 2% of all ectopic pregnancies reported, and this figure is in agreement with that quoted by Keenan (1944). This figure, however, seems very high and is probably an exaggeration, for, as Johnstone (1928) has pointed out, there must be many series of tubal pregnancies numbering 100 or more but containing no example of the interstitial variety.

CASE REPORT

A 3-gravida 2-para aged 29 was admitted as an emergency case on June 13, 1949. She gave a history of three normal menses following cessation of lactation of her second child, born March 26, 1948. After her last period on March 23,

1949, there had been amenorrhoea until May 24, when a brown offensive vaginal discharge suddenly began without antecedent pain or apparent cause. Two days later there occurred a very profuse vaginal haemorrhage with the passage of many clots. After 24 hours she was able to get up and carry on her household duties, but the loss continued "like the first day of the period" until her admission to hospital three weeks later. Five days before admission she experienced her first attack of abdominal pain. It was central in distribution and a continuous ache in character, being exacerbated by sudden movement, defaecation, and micturition. There had previously been no bowel or micturition symptoms.

The patient's menstruation was normally regular, with a cycle of 30 days and loss of seven days. The menarche had occurred at 16. There had been two normal deliveries, in 1938 and 1948.

The letter from her private doctor contained an outline of the relevant past medical history, and the details were later supplemented by the previous case notes and by correspondence with the hospital concerned. In 1939 appendicectomy was performed in the Bristol General Hospital and convalescence was delayed by peritonitis and wound sepsis. In 1943 right salpingo-oophorectomy was carried out at the Radcliffe Infirmary, Oxford, for chronic salpingo-oophoritis. In November, 1946, she was again operated upon in Bristol for a right ectopic pregnancy. Unfortunately, detailed clinical notes cannot be traced, but there is definite evidence that a right ectopic pregnancy had apparently ruptured into the broad ligament and was densely adherent to the right wall of the uterus, to bowel, and to omentum. The available notes made no mention of the right salpingo-oophorectomy performed three years previously.

Examination on admission revealed a tired, flushed, ill-looking woman. Her temperature was 99° F. (37.2° C.), pulse 90, respirations 20, and blood pressure 125/80. General examination and urinalysis were negative. Her breasts showed equivocal signs of pregnancy. The haemoglobin was 92%. The abdomen was scarred by previous laparotomies. No tumour was palpable, and there was no definite tenderness. There were no signs of free fluid. On vaginal examination the vulva and vagina and their mucosal colouring were normal. The cervix was softened and the os closed; movement was painless, and there was slight bleeding. The uterus was bulky and retroverted, and there was an extremely tender pulsating mass in the pouch of Douglas.

In spite of the unusual history the examination suggested that in the main the most likely diagnosis was that of ectopic pregnancy, but the differential diagnosis was a wide one. The patient was prepared for laparotomy.

Examination under anaesthesia after catheterization confirmed the pre-operative findings. The uterus was anteverted and the pulsating mass could then no longer be felt. After dilatation of the cervix, curettage revealed exuberant endometrium and a sensation of fullness in the region of the right cornu. A large-bore needle was passed through the posterior fornix and frank blood in quantity was readily aspirated. At laparotomy there was a moderate amount of old and recent blood in the peritoneal cavity. The uterus was slightly enlarged and blood was spurting from the site of a ruptured right interstitial pregnancy. The ragged bleeding cavity measured 4 by 3 cm. The anatomy of the right round ligament was normal, but the Fallopian tube and ovary were absent on that side. The left tube was normal, and the ovary contained a corpus luteum. The affected area of the fundus was excised by a V-shaped incision and the uterus refashioned with catgut sutures. The scar was peritonized by a loop of the round ligament. It was particularly noticed that there was no communication between the gestation sac and the cavity of the uterus.

Convalescence was stormy, being interrupted by episodes of paralytic ileus on the second day, wound sepsis on the seventh day, and a discharge of watery purulent material

from the vagina on the seventeenth day after operation. Vaginal examination at this time revealed no abnormality. With sulphonamide and penicillin the temperature settled and the abdominal wound healed soundly. The ileus responded to the usual treatment. The patient was finally discharged 24 days after operation.

The pathologist reported that the specimen, on section, showed a haemorrhagic cavity lined in places by pale clear cells of decidual appearance. No chorionic villi were demonstrated in the sections taken. There was deposition of calcium in the myometrium, and also evidence of myometritis and a salpingitis in the remaining portion of the interstitial segment of the tube.

COMMENT

The difficulty of diagnosing with any certainty an interstitial ectopic pregnancy before operation is well known, and this case was no exception. It is presumed that embryo death and a curiously asymptomatic intraperitoneal rupture took place about May 26—facts compatible with the size of the cavity found at operation. The fresh haemorrhage from the cavity seen on inspecting the uterus was probably occasioned by the preliminary anteversion. The microscopical appearance of a myometritis and interstitial salpingitis was an interesting feature of this case and explained the purulent discharge per vaginam, the wound sepsis, and, partly at least, the post-operative pyrexia.

But perhaps, above all, the case described is exceptional because it demonstrates clearly that on two separate occasions the fertilized ovum transmigrated across the pelvis to become ectopically implanted each time in that portion of the tube remaining after two separate salpingectomies. In Keenan's paper on interstitial pregnancy is mentioned the finding by D'errico of 23 cases of such pregnancy occurring in the stump following the removal of the extrauterine portion of the tube. Such behaviour is an eloquent testimony to the bizarre insistence and persistence of the reproductive function in woman, and it is a reminder of the pitfalls attendant on any operative procedure on the tube devised for the purpose of sterilization.

My thanks are due to Mr. H. L. Shepherd for his permission to publish this case, to Miss M. O. Dunster for her courtesy and help, and to Dr. A. L. Taylor for his pathological report.

The West Middlesex Hospital has for many years been helped by a considerable body of voluntary workers in a great variety of ways (*Third Annual Review*, July, 1950–October, 1951, South-west Middlesex Hospital Management Committee). To co-ordinate the work of these helpers and to give formal recognition to their services a League of Friends of West Middlesex Hospital has been formed. Activities of its members include the sewing on of buttons and tapes in wards, singing and playing to elderly patients, visiting patients without relatives or friends, and help with preparations for special occasions such as Christmas festivities. Members of the Women's Voluntary Services have continued to provide a trolley-shop service in the wards, and they also run a canteen trolley for out-patients. Help of this kind is very much appreciated both by patients and hospital staff, says the report, and the value of the work done by these voluntary workers cannot be over-emphasized. It is hoped that they will continue to give their services and enrol their friends.

Reviews

THE KIDNEY

The Kidney: Medical and Surgical Diseases. By A. C. Allen, M.D. (Pp. 584; 1,115 illustrations. \$15 or £5 5s.) New York: Grune and Stratton. London: J. and A. Churchill. 1951.

This is an important book by an acknowledged authority on the pathology of the kidney. It embodies the latest and, in the opinion of the reviewer, the most successful attempt to correlate the clinical and biochemical aspects of renal disease with structural changes in the kidney. In a series of brilliant and fascinating studies, which include much original work, the author succeeds in demonstrating not only that morbid histology is an active and growing science with much yet to contribute to knowledge of renal disease, but that morphology is still the rock upon which a sound understanding of these disorders must be based. Even such contentious entities as diabetic glomerulosclerosis, haemoglobinuric, osmotic, and cholaemic nephrosis, and the renal complications of disseminated lupus erythematosus and toxæmia of pregnancy, for example, are seen to fall naturally into a logical, if for clinical usage perhaps a trifle cumbersome, system of classification based on morbid histology. The evidence is nowhere strained in order to produce an all-embracing classification, and where gaps occur they are carefully pointed out.

The book includes chapters, in addition to those on the various forms of Bright's disease, on such subjects as embryology, anatomy, normal and abnormal physiology, uraemia, malformations, infections, pyelonephritis, calculi, renal rickets, and tumours, and a useful section on histological artifacts. Each chapter is an accurately informed and balanced review of current knowledge in which the author's personal views, though never obtruded, are clearly apparent. There is a carefully selected bibliography at the end of each chapter, and an adequate subject index concludes the volume. The 1,115 illustrations have been skilfully chosen and most beautifully reproduced. No one interested in the kidney can fail to profit from reading this book, and the author and publishers are to be congratulated on a valuable addition to the literature on the kidney and its disorders.

A. A. OSMAN.

ACTION OF ANAESTHETICS

The Mode of Action of Anaesthetics. By T. A. B. Harris, M.B., B.S., D.A., F.F.A.R.C.S. (Pp. 768; 64 tables, 22 figures. £2 2s.) Edinburgh: E. and S. Livingstone. 1951.

It is immediately evident that Dr. Harris has devoted an immense amount of time and thought to the production of this book, and no experienced anaesthetist could fail to peruse its 700 pages without learning a great deal about the theoretical aspects of his specialty. Each chapter concludes with a copious list of references, while a comprehensive index of 67 pages enables any subject to be tracked down with ease and rapidity.

He discusses at great length the chemistry and biochemistry of the subject, sometimes in terms which are unfamiliar to the average anaesthetist, and the addition of a glossary might be advantageous. The theories advanced are most stimulating to thought, but the beginner should not take them all too seriously or he may become nervous of administering any anaesthetic at all. In some places the author tends to describe the action of drugs as they should be according to current theory rather than as they actually are. For example, few senior men would agree with the description of the cardiovascular effects of cyclopropane and trichlorethylene, although the described effects may occasionally be seen and certainly fit in very nicely with the expected actions from a consideration of their struc-

tural formulae and physical properties. Again, the theory that toxicity increases with the number of chlorine atoms in the molecule is not borne out by experience with isopropyl chloride and trichlorethylene, nor is the suggestion that the jactitations during administration of nitrous oxide are associated with a build-up of carbon dioxide. The idea that cauda equina lesions following spinal analgesia are due to the deposition of the analgesic base is ingenious, but it seems much less likely to be true than the accepted explanation of contamination of the injected solution by the antiseptic in which the ampoules have been kept.

These few examples are not to be regarded as destructive criticism but show how provocative of thought this volume may be. The type and general production are excellent, but shorter paragraphs and more cross-headings would make the text easier to follow.

C. LANGTON HEWER.

ENZYMES

The Enzymes. Chemistry and Mechanism of Action. Edited by James B. Sumner and Karl Myrback. Volume 2, Part 1. (Pp. 790. \$14.80.) New York: Academic Press, Inc. 1951.

This is the third part of this work, the first volume of which (in two parts) has already been reviewed (*Journal*, June 30, 1951, p. 1493). As with the previous parts, each chapter has been prepared by an authority on the subject under discussion. This first part of Volume 2 opens with an erudite and elegant treatment of the theory of oxidation reduction, by the late Dr. Leonor Michaelis, whose classic work in this field is known to all students of enzymology. Then follow four chapters on enzymes which bring about the fission of phosphate-containing substances, the first by N. O. Kaplan on thermodynamics and mechanism of the phosphate bond, the second by Sydney P. Colowick on transphosphorylating enzymes of fermentation, the third by H. M. Kalckar on dephosphorylation of adenosine polyphosphates, and the fourth, on aldolase and isomerase, by Otto Meyerhof. These chapters bear witness to the importance which the biochemist places on "energy-rich phosphate bonds" and their role in the storage of chemical energy and in the processes whereby energy is made available for many different metabolic processes.

The remainder of the chapters cover decarboxylases, co-enzymes, flavin-containing enzymes, iron-containing enzymes, copper-containing oxidases, and enzymes concerned with the metabolism of amino-acids and amines, with the oxidation of unsaturated fats, and with sulphur compounds. The volume closes with chapters on "Anaerobic Glycolysis, Respiration and the Pasteur Effect," by Frank Dickens, and on "Yeast and Mold Fermentations," by F. F. Nord and Sidney Weiss.

It will be seen from the titles how wide is the field covered by the 790 pages of the 21 chapters of this book. Unfortunately, since this book is only the first part of Volume 2, there is no index, and until the second part of Volume 2 is published some inconvenience in the use of the present book will be met with by those who wish to utilize it for general reference. The production of the book is good and the diagrams and illustrations are clear, but it is hardly one to be read by those who wish to browse in the field of enzymology. As an instalment of an encyclopaedic work of reference in the field of enzymes it will find a worthy place on the shelf beside its predecessors.

F. G. YOUNG.

BLOOD DISEASES

Handbook of Diseases of the Blood. By A. Piney, M.D., M.R.C.P. (Pp. 213; illustrated. £1 1s.) London: Harvey and Blythe. 1951.

A patient with a blood disease may quite possibly be seen first by a physician, diagnosed by a clinical pathologist, and treated by a surgeon or a radiotherapist, and in most British hospitals the clinical pathologist holds the key position in this team. Much time and money is spent on the investiga-

tion of patients with obscure and incurable blood disorders, and some people feel that the money would be better used on fundamental research and the prevention of disease. Dr. Piney's complaint, however, is that the system has led to the neglect of bedside observation of patients with blood disorders. He has therefore written this book to supply an almost entirely clinical account of the blood diseases, laboratory aids being described only when they are essential to amplify the results of clinical observation.

Working within this frame of reference, he has produced a book which will be useful to students going up for the higher examinations in medicine. The first chapter is on the symptoms of diseases of the blood and the second on the haematological signs. The actual diseases are then discussed in sequence. The book is lucidly written and well printed. Nevertheless, to those who associate Dr. Piney's name with illustrated books on haematology it will be something of a disappointment, and one cannot help feeling he would have made a better book if he had fused together the material and illustrations in his recent *Synopsis of Blood Diseases*, *Sternal Puncture*, and the present volume. If the student is going to read a separate text on haematology, then he had better get a complete but not too detailed synoptic account, such as Fowler's *Hematology*. Dr. Piney, by restricting his gaze to half the picture, would seem to be in danger of widening the division he deplors.

L. J. WITTS.

HORMONE ASSAY

Hormone Assay. Edited by C. W. Emmens. (Pp. 556; illustrated. \$10.00.) New York: Academic Press Inc. 1950.

The field of biological standardization has increased so rapidly in the last fifteen years that it is no longer possible to comprehend the subject within one book of reasonable size. Dr. Emmens has therefore performed a valuable service by editing a volume on hormone assay, which is a well-defined section of the field, and he has chosen his eighteen contributors with great care. It is interesting to note that eight are from the U.S.A., six are from Britain, three are from Australia, and one is from Denmark.

The reader unfamiliar with the subject will find the book formidable, for the methods are presented by many of the writers with so much statistical matter that the ordinary physiologist or biochemist would find it difficult to follow them. It seems as if the worker in biological standardization has found some statistical treatment essential, and, having mastered a little, has developed an appetite for more and has finally acquired a vocabulary which, while as clear as daylight to him, makes his speech seem like a foreign language to others. It is a pity that this should have happened, since workers in biological standardization have made a great contribution to the design of biological experiments and to assessing the value of the results. The mathematical caution with which they regard their findings could be extended widely with much benefit.

The difficulty arises from the introduction of technical terms. A scientific worker ought to be forbidden to introduce a new technical term unless he has obtained permission from a suitable tribunal, or by the majority vote of a large society, except when the term is self-explanatory. Take the words "analysis of variance." No worker in biological standardization dare admit to-day that he does not understand what it means. Yet how many physiologists understand it? If I quarrel with my neighbour I am "at variance" with him. Has "analysis of variance" anything to do with that? The work of those who are engaged in research is of value only so far as it becomes known to others and understood by them. It can be understood only if it is not shrouded in technical terms. The introduction of a new technical term is therefore not a matter of pride; it should bring a sense of failure that a further obstacle has been put in the way of common intercourse.

The contributors to Dr. Emmens's book are a distinguished group. It is difficult to single them out, but the

articles by Dr. R. I. Dorfman on androgens and on adrenal cortical hormones and by Dr. R. K. Callow on the chemical assay of steroids should be specially valuable to many workers.

J. H. BURN.

CHEST OPERATIONS

Thoracic Surgery. By Richard H. Sweet, M.D. Illustrations by J. R. Arroyo, M.D. (Pp. 345; 155 figures. £2 10s.) Philadelphia and London: W. B. Saunders Company. 1950.

This book sets out nakedly and unashamedly to be what it is—a handbook of chest operations for those surgical artisans who wish to operate on or within the chest. The author gives a fine display of illustrations, designs for operations, and complete tables and summaries of procedures. As would be expected from a surgeon of Dr. Sweet's eminence and ability, he performs his task admirably.

Discussion of the surgery of the thorax, as opposed to mere operating, is scanty, but there are several remarks which are either controversial or reveal the imperfection of the purely technical presentation. The author states that the Semb apicolysis is of no use if the lung is at all rigid. It is disturbing to read that the only aftercare needed for a drained empyema is wound dressing; no mention is made of physical treatment and none of control with pleurograms. We are also informed that chronic empyema is a rare sequel. Would it were so! Also, *horribile dictu*, the Schede operation is revived and described. We are told by word and picture that the best site to divide an adhesion in a case of artificial pneumothorax is midway between its lung and chest-wall attachments. These are almost the only features that one can criticize adversely. The section on the oesophagus is excellent.

It is noteworthy that such a frankly vocational book should have come from the Harvard School of Medicine, whose primary interest is usually in the more academic principles of medicine and surgery. Perhaps Dr. Sweet will later delight us with a second volume on the pure surgery of his craft. In the meantime this volume can be highly commended and strongly recommended to those who wish for a guide to operations upon the thorax.

R. C. BROCK.

ANATOMY FOR NURSES

Applied Anatomy for Nurses. By E. J. Bocock, S.R.N., S.C.M., D.N., and R. Wheeler Haines, M.B., D.Sc., F.L.S. (Pp. 320; 231 figures. 15s.) Edinburgh: E. and S. Livingstone. 1951.

This book is in several respects unusual. The authors describe elementary anatomy and, to a certain extent, the "application" of it, though not so much as the title would lead the reader to expect. In addition they give quite a considerable amount of elementary physiology and histology in language which is clear and sometimes colloquial. Here and there one gleans some interesting and out-of-the-way information—for example, why eunuchs do not go bald, and why osteopathy is incorrect. The illustrations are mostly diagrammatic and explanatory; there are a few which might be called crude. The authors are, we hope, unfair to the surgeon in thinking that a chronic psoas abscess could be mistaken for a local boil or an abscess of the lymph nodes, for a psoas abscess is painless.

The most unusual part of the book is the appendix, which concerns the supply of bodies for dissection. The authors emphasize the urgent need for them, and "it seems fair to ask nurses both to donate their bodies for dissection and to persuade others to do so in suitable cases." This would be a noteworthy form of applied anatomy.

There is certainly much to be learnt from this book.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY FEBRUARY 23 1952

BACTERIAL RESISTANCE TO
CHEMOTHERAPY

The clinical exploitation of a new antimicrobial drug passes usually through two main phases, the first being over-enthusiastic and somewhat indiscriminate, and the second more critical and restrained. One factor in this transition is often the discovery that some strains of an otherwise susceptible organism are, or are apparently becoming, resistant to the drug. This change rapidly reduced the efficacy of sulphonamides in gonorrhoea, and showed signs of threatening the usefulness of these drugs in pneumonia and in streptococcal infections before a powerful reinforcement arrived in penicillin. Of the proportion of these and other bacteria now insensitive to sulphonamides very little is known, but examination of strains of some bacteria from unsuccessfully treated urinary tract infections clearly shows their capacity to acquire resistance. Penicillin has withstood the test of time much more successfully, but it is unfortunate that the one species, *Staph. pyogenes*, which seems to be slowly escaping from its influence is that against which its action was perhaps of the greatest value. Resistance to streptomycin can be acquired so quickly by any species that it stands in a class apart, and the diminishing use of this drug for treating any condition other than tuberculosis is due in part to the increasing prevalence of resistant organisms, although the fashion for the newer antibiotics has been another influence. So far as resistance is concerned it seems that chloramphenicol, "aureomycin," and "terramycin" have a good deal in common: resistance to one—which can certainly develop, although sometimes only to a moderate degree—is accompanied by resistance to one or both of the others, the most closely related pair being aureomycin and terramycin.

In the discussion of this subject in the Section of Pathology of the Royal Society of Medicine on February 5, a report of which appears on page 434, attention was concentrated on the mechanism of the change from sensitive to resistant. There are two

clear examples in the clinical field where the process has evidently been one of strain selection. Sulphonamide-resistant gonococci and penicillin-resistant staphylococci are known or believed to have existed before these drugs were used, and they have naturally gained increasing predominance as sensitive strains have been eliminated. Studies of staphylococci have fortified this belief, since in this species natural resistance and artificially produced resistance to penicillin are of different natures, one depending on penicillinase formation, the other probably on a change in internal metabolism. But when resistance appears in a bacterial population which was previously wholly sensitive, as in a single given culture, either mutation or adaptation must have occurred. Which of these processes is in fact responsible has been a matter of violent controversy. As was pointed out at this meeting, it need not necessarily be assumed that the process is the same for all noxious agents or even for all antibiotics; the evidence in favour of the mutation hypothesis is far stronger in studies of streptomycin than in those of any other drug.

Of perhaps more practical interest is the property or behaviour of the bacterial cell on which resistance depends. At the R.S.M. meeting Gale pointed out that this may be of several different kinds. It may depend on the formation of something which neutralizes or destroys the drug in the environment, the clearest example of this being penicillinase. Resistance may also depend on impenetrability of the bacterial cell wall. Finally, and most often, it can depend on the establishment of an alternative metabolic pathway to one blocked by the drug. There may certainly be more than one of these points of interference with metabolism: the stepwise acquisition of resistance to sulphathiazole by staphylococci is an example of a change appearing to involve different stages of some metabolic process or perhaps actually different processes. Mitchison¹ has made the same suggestion about streptomycin resistance in tubercle bacilli. He found three distinct degrees of this among organisms in a single culture: one explanation of this could be that different concentrations affect either one, two, or three processes which the cell can successively by-pass. A similar assumption has been made by Eagle² to account for the "zone phenomenon" in the action of penicillin. It is well recognized that some bacteria, including *Strep. faecalis* and many strains of *Staph. pyogenes*, are killed at a maximum rate only by an optimum concentration, which may be quite low: above this the effect is retarded. Eagle's suggestion is that the optimum concentration acts at a late stage in some metabolic process, causing

¹ *J. gen. Microbiol.*, 1951, 5, 596.

² *J. Bact.*, 1951, 62, 663.

³ *Ann. Med. exp. Biol. fenn.*, 1951, 29, Suppl. 1.

⁴ *J. Lab. clin. Med.*, 1951, 38, 719.

⁵ *Bull. Johns Hopk. Hosp.*, 1951, 89, 81.

⁶ *Antibiot. and Chemother.*, 1951, 1, 472.

the accumulation of a toxic intermediate product, while high concentrations affect an earlier stage and thus prevent this product being formed. Although a good deal is known from the work of Gale himself and others of certain metabolic gymnastics imposed on bacteria by antibiotics, it does not follow that the effects so disclosed are the only ones caused, or are in fact those which are lethal to the normally sensitive cell.

Some speakers at the R.S.M. meeting also mentioned cross-resistance, a phenomenon which, as already mentioned, may sometimes deprive the three newer antibiotics of separate and successive usefulness (fortunately susceptibility to penicillin seems independent of that to any other drug). On the other hand, this is a relationship which seems to work both ways, because according to Kaipainen³ and Gocke and Finland⁴ habituation to streptomycin or neomycin may actually result in an increase in sensitivity to all three of the newer antibiotics. Still more remarkable and perhaps of clinical importance, although this remains to be proved, is the effect of habituation to aureomycin on a penicillin-resistant staphylococcus first observed by Chandler and his colleagues⁵ and confirmed for this and two other penicillinase-forming organisms of different species by Monnier and Schoenbach.⁶ These workers found that under the influence of aureomycin the organisms ceased to form penicillinase and consequently became sensitive to penicillin. There is much that remains to be explained in observations of this kind, but they may help in piecing together a more coherent view of the mode of action of antibiotics generally. It also seems that, if clinical practice can receive constant and detailed help from the laboratory in individual cases, many an otherwise difficult situation can be overcome. The use of combinations of drugs to prevent the acquisition of resistance to one of them is also a well-founded procedure in specified instances, although it may have unfortunate results if this fact encourages shotgun therapy.

THE SICKLE-CELL TRAIT

The curious tendency of the erythrocytes of some persons to become sickle-shaped has four principal aspects—biochemical, genetical, clinical, and anthropological—interrelated in such a complex manner that any investigation of one of them almost inevitably involves all the others. Of all Africans living south of the Sahara Desert, 15% at a rough estimate have in their red cells a haemoglobin molecule which is physico-chemically abnormal.¹ In the oxygenated condition the molecules are in solution inside the

red cell like normal oxyhaemoglobin. In the deoxygenated state, however, their solubility is greatly reduced and the haemoglobin crystallizes out and distorts the cell into a crescentic or sickle shape. This change of form is readily observed microscopically and is the basis of the routine diagnosis of the condition. The change of form appears completely reversible, but it is possible that repeated changes may lead to haemolysis.

Sickling is inherited as a mendelian dominant: that is to say, inheritance from only one parent is sufficient to give rise to the condition in the offspring, and all who carry the sickling inheritance manifest it in their red cells. Some of them also suffer from a severe chronic anaemia, and the central medical problem is to ascertain why the remainder with sickling red cells apparently stay perfectly healthy. In the superficially similar Mediterranean (Cooley's) anaemia, in which a red-cell abnormality is also inherited as a mendelian dominant, heterozygotes suffer little or no disability, while homozygotes have a severe anaemia, usually fatal in early childhood. A similar view of the pathology of sickle-cell anaemia has tended to prevail in America, where the red-cell condition is present in only about 10% of negroes, implying about 0.5% of homozygotes. The hypothesis that the latter are all affected by anaemia has recently received strong support from the genetical work of Neel,² by whom it was originally put forward. Pauling and his colleagues¹ have moreover shown that all of the haemoglobin is abnormal in cases of anaemia but only part of it in sickling without anaemia.

In Africa, on the other hand, the frequency of sickling is over 20% in many populations, and reaches 45% in at least one. This implies a frequency of 1–6% of homozygotes. When other coincidental causes of anaemia are discounted in sickling individuals the frequency of true sickle-cell anaemia in Africa is certainly under 1% and probably very much lower than in America. Two main hypotheses have been put forward to explain this discrepancy. One is that under African conditions homozygotes nearly all die before or soon after birth. But it is almost inconceivable that the sickling frequencies found in some African populations could be maintained in face of such mortality. The other hypothesis is that the sickling gene causes anaemia only when inherited with another gene or genes derived from a European ancestor, which is likely to be much commoner among American than among African

¹ Pauling, L., Itano, H. A., Singer, S. J., and Wells, I. C., *Science*, 1949, 110, 543.

² *Blood*, 1951, 6, 389.

³ *Amer. J. clin. Path.*, 1951, 21, 858.

⁴ *Ann. Eugen.*, 1949, 14, 279.

⁵ *Nature, Lond.*, 1949, 164, 494.

negroes. This problem will not be solved until further genetical studies have been carried out in Africa, as well as in America. Singer,³ in an admirable and scholarly review with a full bibliography, has recently surveyed the whole question.

The sickle-cell trait has hitherto been recognized only in Africans, in American negroes, in Yemenite Jews, in a small pocket of persons in Greece, and in a few scattered individuals of Mediterranean origin. It has thus been a reasonable assumption that sickling originated in Africa and that its occurrence elsewhere was evidence of African ancestry. In Africa its distribution has been the subject of numerous studies, but the only extensive ones which give full anthropological details are those of Beet⁴ for Northern Rhodesia, and of Lehmann and Raper⁵ for Uganda, and much remains to be done before the significance of this limited distribution can be seen. Two papers elsewhere in this issue report new facts about the distribution of the sickle-cell trait.

Drs. D. B. Jelliffe and J. Humphreys have examined 1,881 of the Yoruba of Nigeria. They found sickling in an overall frequency of 23.7%. In 51 infants under 2 weeks old sickling was absent, but no significant differences were found between the frequencies in the other age groups. There is thus no evidence for any differential mortality, as would be expected if the hypothesis were correct that all homozygotes suffer from sickle-cell anaemia, and that the rarity of this disease in Africa is due to the early death of affected individuals. To disprove this hypothesis completely, however, needs a statistical study of even larger numbers, or a detailed genetical study of numerous families. The absence of sickling in the youngest infants is explained by the authors as due to the persistence of the foetal type of haemoglobin to the exclusion of the sickling type. The article contains an admirable survey of the literature which, though shorter, will be more accessible than that of Singer to British readers.

The research of Dr. H. Lehmann and Miss M. Cutbush, on the other hand, was designed to test the hypothesis held by some anthropologists that the present population of most of tropical Africa contains an important component derived from Asia. This putative ancestry might be the source of one or both of the two most characteristic simple genetical characters of Africans, the sickle-cell trait and the Rh chromosome cDe, or R₀. Dr. Lehmann and Miss Cutbush have now found sickling in many members of three of the aboriginal tribes of Southern India. The overall frequency was 13%, but of the Irulas as many as 30% show the trait, a frequency higher than in most African populations so far tested. The cDe combination of Rh

genes occurs in these Indian populations, however, with only a small fraction of the high frequency found throughout tropical Africa. Thus the sickle-cell trait cannot have been transmitted to Indians by a population genetically similar to modern Africans. Either it arose independently in the two areas, or, as is rather more probable on genetical grounds, it was inherited by the peoples of both areas from common non-African ancestors, with an Rh blood group composition different from that of present-day Africans though possibly like that of modern South Indians. This work thus provides results of great anthropological interest: medically it is important in adding yet another possible cause of chronic anaemia to the many known in India.

HABITUAL ABORTION

Attempts to determine the cause of habitual abortion, the condition in which consecutive abortions (usually three or more) occur without intervening pregnancies going beyond the 28th week, have so far been fruitless. Investigations on these patients in the non-pregnant intervals have brought to light little of contributory interest. Three possible groups of causes—paternal, maternal, and foetal—may exist. Some seminologists believe that seminal fluid containing many morphologically abnormal spermatozoa is likely to be responsible for abortion, but no one has shown that the husbands of women complaining of habitual abortion have characteristically abnormal semen. The possible maternal causes which have received most attention are vitamin deficiencies and hormonal inadequacies. Foetal causes include abnormalities of the ova and of the zygote not apparently due to abnormality of the maternal environment. The last two groups of causes deserve further comment.

The elegant studies of Hertig and Rock¹ on abnormal ova are very relevant to the question of foetal causes. From a series of 136 potentially pregnant women they recovered 28 early conceptuses. Twelve of these early ova were abnormal, and of these seven were certainly destined to abort. Four of the latter might not even have caused clinical signs of pregnancy because of their extreme abnormality. Yet in every case the endometrium showed normal secretory development. It was concluded that many spontaneous abortions could be attributed to foetal abnormalities, and that maternal causes were of minor importance.

The vitamin deficiencies which have been suggested as possible causes of abortion are those of C, K, and

E. Evidence on the implication of the first two of these has been presented by Javert and Stander² and by King.³ Swyer⁴ has pointed out that, whereas this evidence has not confirmed the existence of vitamin-C deficiency in aborting women, prothrombin deficiency was present in a significant number of cases. The literature on vitamin E is very extensive, and the value of this substance in the prevention of repeated abortion seems to have been both accepted and rejected in almost equally uncritical fashion. Some years ago Bacharach⁵ reviewed the findings of Vogt-Möller^{6, 7, 8} and of Watson and Tew⁹ and compared their results with the findings of Malpas¹⁰ on the likelihood of the successful completion of pregnancy after a series of previous abortions. Bacharach concluded that the chances of the differences between the published results of treatment in cases with two, three, and four previous abortions and the expected results with untreated cases being exceeded on the basis of random variation were 1 in 200, 1 in 10¹⁰, and 1 in 10⁴⁰, respectively. Either the observations reported by the two groups of workers are fallacious or else there would appear to be strong evidence in favour of the therapeutic efficacy of vitamin E in habitual abortion—unless the outcome of pregnancy in untreated cases is generally more favourable than Malpas's figures suggest.

Hormonal inadequacies as maternal causes of habitual abortion have been conceived in terms of progesterone—and perhaps oestrogen—deficiency. No direct evidence of such deficiency appears to have been adduced, though a suggestion which would dispose of this objection is that a suddenly developing deficiency—such as before the placenta fully takes over the production of hormones from the corpus luteum—is the cause and not a persistently low secretion. At all events oestrogens have been claimed¹¹ to give 77% successful results in patients with habitual abortion, and progesterone by injection is very commonly administered to such patients, though evidence of its efficacy is lacking. The use of implants of progesterone seems to be a logical way of ensuring that the amount of hormone in the blood is kept steady, and is preferable to the erratic and evanescent effects of oily injections. In a recent paper in this *Journal* Drs. P. M. F. Bishop and N. A.

Richards¹² published their further experiences with this treatment. In a combined series of 85 patients their success rate proved to be 85% in those women who had had two previous abortions and 72% in those who had had three or more. Compared with the expected success rates calculated by Malpas and of Eastman¹³ these certainly represent a significant increase. It is, however, a little disturbing that vitamin E, oestrogens, and progesterone implants should all have the same success. The fact that Bevis¹⁴ has obtained equally good results by investigation without treatment raises the question whether it is only the psychotherapeutic effect of all these various regimes that is responsible for the pregnancies going to term. Another doubtful point is that, though Malpas's and Eastman's figures may have applied to the populations they were studying, they may not, nevertheless, have universal validity. Indeed, if Eastman's calculation (shown in Table V in the paper by Bishop and Richards) is carried one step further, the spontaneous cure rate for women with four abortions should be 1%—which simply is not true. Bishop and Richards point out that the obvious way to settle the question whether a progesterone implant is endocrinologically or merely psychologically therapeutic is to treat alternate cases with implants of progesterone and an inert compound such as cholesterol. It would be even simpler to leave the alternate patients without any specific treatment, as Dr. D. C. A. Bevis implies in a letter published in this week's *Journal*, for it might then be found that the spontaneous cure rate is far higher than has generally been supposed.

LOCATING BRAIN TUMOURS WITH ISOTOPES

In 1948 Moore and his co-workers found that the dye sodium di-iodofluorescein was substantially concentrated in brain tumours after intravenous injection.¹ After administration of this dye made with radioactive iodine a tumour in the brain could be discovered by the increased quantity of gamma radiation detected outside the intact skull. It was found possible to deduce the probable position of such a tumour within the brain by measuring the radiation at different points on the head's surface. The possible errors and pitfalls of this method of pre-operative diagnosis are many, but subsequent research by Moore, Selverstone,² and Ashkenazy in particular has (at least in the hands of these original workers) made the location of malignant gliomas very accurate.

Other substances which are concentrated in brain tumour tissue and have been used in large series of cases³ are compounds of radioactive potassium (K⁴²) or phosphorus (P³²). Unlike radio-iodine, which emits long-range penetrating gamma rays, atoms of radioactive phosphorus give out β -particles which have a range

in the brain of only a few millimetres and are hence of value only in delineating the extent of a tumour when the cortex is exposed at operation. For this purpose a needle 2 or 3 mm. in diameter, with a Geiger-Müller counter near its tip, is used to probe the suspected area of the brain. As the needle reaches tumour tissue the counting rate of β -particles rises considerably, as judged by a rush of clicks in the headphones, so that the operator can obtain an idea of the depth and extent of the neoplasm, whereas naked-eye information may be quite inadequate. Radioactive potassium emits both gamma rays and β -particles, so that it should be possible to utilize it both before and during operation. However, there is little in the literature so far to indicate how successful this may be.

Attempts in Britain at confirming the American work on di-iodofluorescein have not met with great success. It is well to bear in mind how very exact any new method of location must be before it improves upon the well-tried techniques of ventriculography and arteriography. Loyal Davis⁴ states that in his series of 340 patients investigated with di-iodofluorescein 95% accuracy was obtained, whereas "pneumography is 65% focally and 85% diffusely accurate." Many neurosurgeons and neuroradiologists in this country would, however, claim 95% accuracy by means of air-study and angiography. Radioactive potassium is unsuited to the location of tumours in the posterior fossa owing to the high counting rate obtained from the adjacent suboccipital muscles; location in this region has become extremely efficient by modern methods of encephalography and vertebral angiography.

There have, however, emerged several indisputable advantages to the patient and to the neurosurgeon. The use of these radioactive isotopes in the doses employed is without immediate harm to the patient, whereas contrast studies of the ventricles and the vascular tree may have very real dangers in subsequent complications. A patient whose condition demands investigation for the presence of a tumour even though such a diagnosis is considered unlikely can more readily and justifiably be subjected to a radio-isotope test than to a procedure having a known morbidity and mortality. The most impressive practical advance so far is the ability at operation to select a region in the brain giving a high count of β -particles after intravenous injection of radioactive potassium or phosphate ions. A biopsy can thus be obtained in the certainty that the pathologist will find a tumour within the small portion removed. Without this aid biopsy not infrequently fails owing to the difficulty at operation of distinguishing neoplastic tissue from neighbouring brain. Such an aid to diagnosis will, however, necessarily always be confined to those hospital centres which are suitably equipped and possess a physicist, since the handling of radioactive substances in bulk involves very special risks to the staff.

It is too early to assess this interesting work on radioactive isotopes in the central nervous system, yet it seems possible that, with the further development of

more sensitive instruments and of substances having still greater differential affinity for neoplastic tissue in the skull, advances will be made in the treatment of brain tumours, particularly of the malignant glioma.

BACTERIAL PRODUCTS AGAINST CANCER

The clinical treatment of human tumours with bacterial products was introduced 75 years ago by Fehleisen, Bruns, Coley, and others. Coley used a preparation made from cultures of streptococci and of *Bacillus prodigiosus* which was called "Coley's mixed toxins." The Council on Pharmacy and Chemistry of the American Medical Association included this preparation in the list of remedies used for the treatment of cancer, although with some misgivings ("Its use in definitely inoperable cases may be quite justified, in many instances, as a desperate attempt to combat the inevitable"). This type of therapy was never widely used; for its successes were rare, and its administration was frequently followed by high temperature, nausea, and vomiting. However, interest in bacterial products as anti-cancer agents was renewed by the work of Gratia and Linz on animal tumours, and encouraged soon after by the experiments of Shear and Andervont on the separation of a polysaccharide, inducing haemorrhage in tumours from broth cultures of *Bacillus coli*. The active fraction was extraordinarily potent, for 0.4 μ g. of the polysaccharide induced haemorrhage in transplanted sarcomata in mice. Concentrates of the polysaccharide contained, after tryptic digestion, a small amount of firmly combined phospholipid, the removal of which destroyed the potency. Other kinds of mouse tumour reacted similarly; for example, spontaneous mammary carcinoma, the Ehrlich mouse carcinoma, and primary sarcoma induced with methylcholanthrene-choleic acid or with 3:4 benzpyrene. With filtrates from *Serratia marcescens* (*Bacillus prodigiosus*) the minimum dose required to induce haemorrhage in 50% of the tumours was found to be 0.1 μ g. of the polysaccharide.

It was observed that mice bearing tumours were much more sensitive to the toxic effects of the agent than were normal mice. In one experiment a fifth of the dosage which just failed to kill normal mice was fatal for two-thirds of a series of mice bearing primary sarcomata. The changes in the tumours, haemorrhage and necrosis, appeared a few hours after injection of the polysaccharide. Complete and permanent regression of the induced tumour occasionally occurred, but usually some part of it survived and grew vigorously after most of the original growth had been destroyed. It soon became clear that the therapeutic dose was dangerously near the toxic dose, for apparently the breakdown of much tumour tissue released some highly toxic material. According to Shear,¹ "It thus appeared that the death of the tumor-bearing mice was largely ascribable not to the toxicity of the polysaccharide itself, but to some phenomenon resulting from the reaction of sensitive tumor tissue to the polysaccharide. The mice

with tumors exhibited symptoms resembling those of shock—namely, prostration, labored respiration, muscular atony, lowered body temperature, etc.; in tumor-bearing patients this agent produced a fall in blood pressure. . . .” Some clinical trials with the polysaccharide did not prove successful either.²

The chief exponent of polysaccharide therapy has thus to admit that this method is far from ideal. An immense amount of work has been devoted to chemotherapy in cancer, but of the thousands of compounds which have been tried out probably oestrogen for prostatic cancer represents to date the only success. There are now indications that this line of attack is losing some of its momentum, probably owing to a number of factors. For example, the screening of numerous compounds for tumour-inhibitory activity tends to become a collaboration between the synthetic organic chemist and the biologically trained technician, where the cancer investigator himself finds little intellectual stimulation. Secondly, the failure of so many potent tumour inhibitors to behave as practical anti-cancer drugs suggests that there is too close a similarity between neoplastic and normal cells for an agent to be able to destroy the one without seriously damaging the other.

Recent work on the role of dysgenic and environmental factors as causes of cancer suggests the possibility that the solution of at least some problems of cancer will come from quite a different direction—namely, by prevention instead of by treatment.

DIFFUSION RESPIRATION

Can respiration occur without respiratory movement? The question is again asked by Drs. Enghoff, Holmdahl, and Risholm, of Uppsala University, who describe in a recent paper¹ the establishment of “diffusion respiration” in man. This phenomenon was named by Draper and Whitehead,² who found from experiments on dogs that under certain conditions blood can be normally oxygenated by the lungs without respiratory movement and rhythmical changes in intrapulmonary pressure. They explain this by describing the action of the “haemoglobin-oxygen pump.” During apnoea oxygen is removed from the alveolus by haemoglobin, but the normal elimination of carbon dioxide ceases. Carbon dioxide is retained in the blood and tissues, and the amount of oxygen leaving the alveolus during apnoea is therefore greater than the amount of carbon dioxide entering it. The pressure within the alveolus thus falls below that of the atmosphere, and movement inwards of the dead-space and atmospheric air occurs.

Three conditions must be fulfilled for this form of respiration to occur: the gas entering the glottis must be mostly pure oxygen, for if air is breathed nitrogen accumulates in the alveoli and quickly causes asphyxia; the airway must be perfectly free; the circulation must be adequate, as the capacity of the “pump” is proportional to the volume of reduced haemoglobin flowing through the alveolar capillaries. Diffusion respiration has been found effective in animals for 30 minutes; but after this the oxygen content of the blood falls, probably because of the Bohr effect—a consequence

of the action of CO₂, with respiratory acidosis and low blood pH.

Enghoff and his co-workers induced apnoea in the human with an intravenous barbiturate and curare. A cuffed endotracheal tube was first passed under general anaesthesia, and the patient was allowed to breathe oxygen from an anaesthetic machine for 10 minutes. The tracheal tube was then connected to a spirometer containing oxygen, which operated without exerting measurable positive pressure. Apnoea was maintained for about 5 minutes, the maximum being 7 minutes 20 seconds. The oxygen consumption during this period was the same as during the time when respiratory movements were still taking place. At the end of the period of apnoea the blood oxygen had not fallen, but the carbon dioxide had increased; no changes were noticed in the functioning of the heart and circulation.

The mechanism of diffusion respiration must not be confused with the insufflation process which was first described by Hook³ in 1667 and was introduced into anaesthesia by Barthelemy and Dufour⁴ and Meltzer and Auer⁵ in the first decade of this century. These workers kept the lungs distended by gases under pressure; in diffusion respiration no pressure is applied, and apnoea is a result of respiratory paralysis. Meltzer and Auer shortly afterwards admitted their technique to be unsatisfactory, which was generally agreed by their contemporaries. Moreover, they do not appear to have maintained distension of the lungs but interrupted the pressure intermittently, so turning their method into one of artificial respiration. Diffusion respiration is more like the phenomenon described a little earlier by Volhard⁷ and Hirsch,⁶ who experimented to discover if ventilation of the trachea would be sufficient to allow adequate respiration to take place. Oxygen at a low pressure was administered through one-half of a double endotracheal cannula, and the animal's respiration stopped with curare; they found that if respiratory movement was restored within an hour the animal recovered, but after longer periods it died. If the oxygen was replaced by air death occurred rapidly.

The oxygen content of the blood was maintained during Volhard's experiments, but the content of carbon dioxide was trebled and death occurred from carbon dioxide poisoning. This observation has achieved a new importance since curare has been used in the operating theatre as freely as in Volhard's laboratory, and the anaesthetist's technique of artificial or assisted respiration has as its object the efficient removal of carbon dioxide as much as the supply of oxygen. Diffusion respiration is a physiological freak which appears to have no clinical application; whether it occurs at all is questioned by Conroe and Dripps,⁸ who suggest that the alveoli are not stationary but oscillated by cardiac movement.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

ANAESTHESIA FOR MINOR PROCEDURES

BY

WILLIAM W. MUSHIN, M.B., F.F.A.R.C.S., D.A.

Director, Department of Anaesthetics, Cardiff

For most minor operations the anaesthetic is also of a minor character. As such it should be characterized by a high degree of safety, simple equipment and method of administration, pleasant sensation and memories to the patient, speedy recovery, and, not least, effectiveness for the surgeon. The occasional anaesthetist, however, must not be misled into thinking that, because the proposed surgical procedure is a minor one, the anaesthetic for it will for a certainty present no difficulty or that little skill will be required. Many examples of the reverse come to mind. The patient with submaxillary cellulitis may need but a small incision, but, as is well known, he may well die before the surgeon even starts his little operation. The child who is to have a small cut sutured may regurgitate a piece of the apple he was eating when he fell down and cut himself, and die of acute respiratory obstruction therefrom. The much-tattooed, burly seaman who is to have an easy dental extraction may be in the chair for only a few minutes, yet his short stay may not only leave its mark both on the dentist's furniture and on the anaesthetist's reputation, but the momentary anaesthesia required may have been obtained only at the cost of extreme and dangerous anoxia. These examples are given here, not to frighten the general practitioner, but to put him on his mettle and to forewarn him never to relax his awareness of possible, though happily rare, difficulties and dangers.

Children

Examples of common minor operations in children for which the practitioner is likely to be asked to give an anaesthetic are circumcision, tonsillectomy, the setting of a greenstick or other fracture, and the opening of an abscess. Before any such anaesthetic a hypodermic injection of atropine should always be given. Up to the age of 2 years a suitable dose is 1/200 gr. (0.32 mg.); from 2 to 5 years, 1/150 gr. (0.44 mg.); and from then onwards 1/100 gr. (0.65 mg.)—all these being given about half to one hour before the operation. In the case of children over 2 or 3 years old, $\frac{1}{4}$ to 1 gr. (32 to 65 mg.) of pentobarbitone sodium by mouth two hours beforehand will make the child placid or even sleepy and fear and crying will be largely obviated.

For the anaesthetic itself many drugs and techniques are available, but for young children and infants the best method of all for the practitioner, as indeed it is for the specialist, is an induction with either ethyl chloride or vinyl ether, followed by ether dropped on to a gauze mask. The ethyl chloride should be administered cautiously, squirt by squirt, but only until the child ceases to struggle, for its purpose is not so much to produce full anaesthesia as to subdue the child and to depress its reflexes enough for it to breathe without restraint the more irritant ether vapour. The addition of ether to the mask is then started. Should insufficient ethyl chloride have been given and the child respond to the ether by breath-holding, coughing, or swallowing, a little more ethyl chloride can be given. By this means overdosage with ethyl chloride is avoided. It is rarely necessary to use gamgee between the mask and the face; certainly this should

not be done in the hope of avoiding an "anaesthetic eye," for this condition, though it may possibly be caused by the anaesthetic coming in contact with the cornea, is more commonly the result of rubbing the cornea with gauze or a towel. Oil should not be put into the eye before or during an anaesthetic, because any ether in the vicinity will surely dissolve in the oil.

For children over the age of about 7 or 8 years nitrous oxide, oxygen, and a little ether may be administered from a Boyle apparatus in the manner described for adults, although even for these older children open drop-ether anaesthesia is most effective and very suitable.

After an operation lasting a few minutes recovery from ether anaesthesia of this sort is very rapid and, apart from perhaps an occasional single vomit, the child is none the worse. It may be put to sleep in its mother's arms or even sitting up on a chair or on the operating table if the anaesthetist thinks it will be kinder. As soon as the child is under, it should be placed on an operating table so that its airway may be properly controlled and the anaesthetic administered. An artificial airway is generally unnecessary in infants and children and should on the whole be avoided, as more likely to be traumatic than helpful. Respiratory obstruction is more often due to the anaesthetist's fingers holding up the infant's lower jaw than to leaving it alone.

When the operation is over the child should be placed on its side and carefully watched until consciousness returns, so that respiratory obstruction or vomiting can be dealt with. A good guide in this respect is not to let the child go back to the mother until it has recovered enough to cry.

Adults

Common examples of minor procedures are incision of septic finger or abscess, the setting of a minor fracture, biopsy, and removal of an ingrowing toe-nail. As the patient is likely to be ambulant and will want to return to that state as soon as possible after the operation, premedication of any sort is best avoided. In very nervous patients this view may be relaxed somewhat, but even two or three aspirin or codeine compound tablets half an hour before the operation, or a $\frac{1}{4}$ -gr. (32-mg.) capsule of pentobarbitone sodium one hour before, will have the right effect without interfering very much with the patient's rapid recovery after the operation, apart from the need to refrain from driving home in a car.

The most suitable anaesthetic for these little operations is nitrous oxide and oxygen, with, if necessary, a trace of trichlorethylene added to the gases before the operation starts. The induction of anaesthesia should not be hurried; it is a common but erroneous belief that nitrous oxide anaesthesia is a quick method. The more slowly induction is carried out the smoother will the subsequent anaesthesia be. Induction is started with pure nitrous oxide and after a few breaths oxygen is added in gradually increasing amounts till, finally, a mixture of about 1.5 litres a minute of oxygen and about 7 litres a minute of nitrous oxide is being given. An average time for induction is 7 to 10 minutes. The trichlorethylene, when it is to be used, should be added cautiously to the gas mixture soon after the start, and as soon as the patient is breathing regularly it should be turned off. Poor anaesthesia is more often due to insufficient oxygen than to too much. The patient's colour should in general be a bright crimson and in any case never worse

than a slightly dull pink. Any obvious cyanosis indicates that more oxygen should be added to the mixture. It is better to use a little trichlorethylene than to cut down the oxygen.

Elderly People

With old people, and indeed with ill and feeble patients in general, particular care should be taken that at no time is the oxygen supply inadequate. The patient's ears should remain crimson the whole time. In these patients more than in any other is it preferable to add a little trichlorethylene to the gas and oxygen than to run the real risks of insufficient oxygenation.

Dental Extractions

These patients form a group in themselves. In young children ethyl chloride or vinyl ether on an open mask is suitable, while for older children nasal nitrous oxide and oxygen may be used, the anaesthetist erring on the side of too much oxygen rather than the reverse. In adults, nasal nitrous oxide and oxygen from an apparatus such as the Walton or McKesson is the routine everywhere. These machines allow slight positive pressure to be used and permit the oxygen percentage to be varied easily without upsetting the pressure. The technique of continuous nasal nitrous oxide is soon learned. The secrets for success are a proper position of the patient in the chair, in which the head is in a natural relation to the body, being neither extended nor flexed; an unhurried induction; satisfactory insertion of a gauze mouth-pack so that debris is held without the respiration being obstructed; the use of slight positive pressure; and adequate support by the anaesthetist of the patient's head and jaw during the extraction.

Thiopentone

This substance is extremely valuable for putting a patient to sleep in a pleasant manner. Its use as the sole anaesthetic, however, should be attended with the greatest of caution. Many fatalities and near fatalities have occurred because the anaesthetist has failed to realize that this drug, while having marked hypnotic properties, is a poor analgesic, and that it will not prevent reflex movement to pain until enough of the drug has been administered to practically stop breathing.

In practice a 5% solution is made up and injected through a fine needle very slowly, allowing plenty of time for the drug to circulate, until the patient is unconscious. For the average fit adult this dose will be about 0.25 g. (5 ml. of 5% solution). Great care is taken that the injection is into a vein and not into the tissues or into an artery. In the former instance the swelling outside the vein is usually obvious, while the patient complains of pain at the site of injection. In the latter the most constant symptom is severe pain of a burning character in the hand. The dire results of intra-arterial injection make it imperative to avoid any veins which lie contiguous to an artery or in a position where an aberrant artery is likely to be found.

Once the patient is asleep the injection should be stopped and the anaesthetic continued with nitrous oxide and oxygen, with or without trichlorethylene. If it is the wish of the anaesthetist to use thiopentone as the sole anaesthetic, the patient's reaction to pain should be tested as soon as he is unconscious. For example, the surgeon might prick the skin with his knife. If necessary another small amount should be given and the patient tested again. This manoeuvre is repeated until no movement takes place. The habit of arbitrarily deciding on what the single dose is to be, and then injecting, is to be condemned, because in this way overdosage easily occurs. The reaction of patients to thiopentone varies widely and it is nearly impossible to judge this merely by looking at them beforehand. It is almost certain that respiration will be very depressed or even absent at the moment that the patient no longer reacts to the operation. When he is robust and the dose of thiopentone

correct, respiratory activity quickly recovers spontaneously. If breathing does not start or regain its vigour within a minute or so the anaesthetist should not hesitate to resort to artificial respiration, by squeezing the chest, or better still by a squeeze of the reservoir bag, or by blowing with the lips down a facemask held on to the patient's face so that his lungs are inflated. Recovery after thiopentone is markedly slower than after nitrous oxide and a period of drunkenness may persist for some hours.

Though no more apparatus than a syringe and needle is required, the less obvious but more important ingredients for safety with thiopentone are caution and long experience. The practitioner will have less anxiety and have better success with his minor anaesthetics if his first inclination is towards inhalation anaesthesia rather than intravenous for any but the most minor of minor procedures.

Difficulties

Respiratory Obstruction.—The practitioner should beware of anaesthetizing patients with marked respiratory obstruction. These patients may die very quickly as soon as they are made unconscious and unable to use the accessory muscles of respiration on which perhaps their life was depending. These cases, though the surgery may be small in extent, call for the greatest skill and experience on the part of the anaesthetist. Little more will be said about them here, except that the essence of safety is to relieve the respiratory obstruction before the patient is made unconscious.

Vomiting.—If the patient is known to have had food within three hours of the anaesthetic it is better to postpone the operation rather than to risk the very grave dangers of regurgitation and inhalation of vomit. Many patients die each year from this cause, although they were having a simple anaesthetic for a minor operation. In cases of emergency it is justifiable to empty the stomach by passing a large stomach tube just before the anaesthetic is begun. The gravity and danger of inhaling vomit cannot be over-emphasized, as also the fact that this may occur with the most trivial procedures. In these instances the tragedy is all the greater.

Resistance to Anaesthesia.—The practitioner may find that patients who are excitable, in great pain, addicted to alcohol, or generally robust may be difficult to subdue enough to remain immobile during the operation. When this occurs he should not hesitate to add trichlorethylene to the nitrous oxide and oxygen and allow plenty of time for this drug to take effect. If this difficulty is anticipated, because of reports of previous anaesthetics from colleagues or the patient himself, premedication such as that mentioned above should be ordered; when this is impracticable an intravenous injection of 10 to 15 mg. of pethidine may be given just before the anaesthetic is started.

Fire and Explosion

The practitioner should bear in mind that both ether and ethyl chloride are highly inflammable substances. They should never be administered in the presence of an open flame of any sort or of any other obvious source of ignition. Smoking in particular should never be allowed in the vicinity of an anaesthetic. The addition of oxygen to either of these substances makes them highly explosive, and if such a mixture is ignited a violent detonation may occur, with grave injury to the patient and perhaps structural damage to the room. Whenever a diathermy is to be used or the anaesthetic is to be administered in the presence of an open flame, nitrous oxide alone or with some trichlorethylene, or thiopentone, should be the anaesthetic selected. Chloroform cannot easily be justified except in unusual circumstances for a minor operation, in view of the availability of the alternatives mentioned and of the known dangers of cardiac arrest, of overdosage, and of late poisoning, the incidence and occurrence of all of which are now established beyond reasonable doubt.

Post-operative Care

The patient should be allowed to recover from his short anaesthetic in his own time and no attempt made to waken him by slapping his face or other manœuvre. Even after consciousness has returned, enough time should be allowed for him to feel really recovered before he gets to his feet. On no account should a patient be allowed to drive a car after an anaesthetic, or even to go out into the street unless accompanied by another adult. Although apparently normal, a period of post-operative mild drunkenness and disordered judgment may persist for some hours, particularly if more than the smallest amounts of trichlorethylene or thiopentone have been used.

"THE FOUNDER OF SCIENTIFIC SURGERY"

HUNTER MEMORIAL AT ST. MARTIN'S

The President and members of Council of the Royal College of Surgeons, with members of the Hunterian Society and others, attended at St. Martin-in-the-Fields on February 14 when a tablet in the crypt was unveiled and dedicated recording the fact that the body of John Hunter had rested in the vaults of that church from 1793 to 1859, when it was removed to Westminster Abbey. After the General Thanksgiving and prayers the President of the College (Sir Cecil Wakeley) read a lesson from the Wisdom of Solomon:

"For God himself gave me an unerring knowledge of the things that are, to know the constitution of the world, and the operation of the elements . . . the natures of living creatures and the ragings of wild beasts, the violences of spirits and the thoughts of men; the diversities of plants and the virtues of roots: all things that are either secret or manifest I learned, for she that is the artificer of all things taught me, even wisdom."

The clergy and a part of the congregation then proceeded to the crypt, where Sir Henry Dale unveiled the tablet, which was dedicated by the Dean of Westminster. When they

interred in the Abbey between the graves of Ben Jonson and Charles Lyell. Words written by J. F. South, then Junior Vice-President of the Royal College, and contained in the ornamental brass which covered Hunter's remains in the Abbey, doubtless mirrored the views of surgeons nearly 70 years after his death:

"A gifted interpreter of the divine power and wisdom at work in the laws of organic life . . . the founder of scientific surgery."

To this day they saluted one "who was great through mortal days and died of fame unshorn."

After this homage to the great shade of Hunter, Sir Gordon Gordon-Taylor proceeded to speak of Frank Buckland, whom the tablet also commemorated, describing him as a somewhat erratic surgeon-anatomist, a great investigator in natural history, with a bias for turning to practical use the facts he ascertained, and, like Hunter, a great collector. He formed a fish collection which he left to the Science Museum, South Kensington, and his work was continued by the Buckland Research Foundation in gathering together and summarizing knowledge, especially recently acquired knowledge relating to important food fish.

A third name, he added, inevitably stole into the thoughts of some of them, for it was owing to the zeal and enthusiasm of the late George Grey Turner that the project to place the plaque in the church had come to fruition. With many a difference between them, Hunter, Buckland, and Grey Turner were all great collectors and fervent believers in the value of the museum; all three were incessantly industrious, and all died immersed in the work they loved. Their name and life and work would endure long after any memorial in stone had perished. In the great words which Thucydides put in the lips of Pericles in his famous funeral oration over the Athenian dead: "The whole earth is the tomb of great men. Neither is their name graven only on stone which covers their clay, but abideth everywhere without visible symbol, wrought in the stuff of other men's lives."

Nova et Vetera

AN ANCIENT MEDICAL COMPENDIUM

Caelius Aurelianus: On Acute Diseases and on Chronic Diseases. Edited and translated by I. E. Drabkin. (Pp. 1,019. £5 12s. 6d.) Chicago: University of Chicago Press. London: Cambridge University Press. 1951.

One of the most versatile of the ancient Greek physicians was Soranus of Ephesus, who flourished about 100 A.D. He wrote on almost every aspect of medical theory and practice, as well as on philosophical and other subjects. Most of his works have disappeared. His gynaecology, however, survives in some very peculiar, very early, and very famous illustrated manuscripts, the influence of which persisted for fifteen hundred years and may still be traced. Of his other writings by far the largest and most complete, though lost in the original Greek, has come down to us in a Latin version prepared in the fifth century by one Caelius Aurelianus of Numidia, the modern Morocco. This work is an immense treatise in two parts, one on acute and the other on chronic diseases. The manuscripts of this Latin translation have also been lost, so that the modern editor must rely on editions of the sixteenth century, making such emendations as his skill in scientific literary criticism will permit. Such an edition has hardly been attempted since 1709, so that Professor Drabkin has, in effect, been working in a new field, hitherto almost untouched by modern scholarship. An edition of Caelius Aurelianus has long been regarded as a special need of Latin scholarship, for it has points of linguistic as well as of medical interest.

In the later pre-Christian and the earlier Christian centuries medical thought developed into various sects or "schools" founded on different philosophic principles. The most prominent, and for long the most influential, of these was the so-called "Methodist," to which Soranus and his

had returned to the church a commemorative address was given by Sir Gordon Gordon-Taylor, who narrated briefly the circumstances attending the discovery and identification of John Hunter's remains.

Identification of Hunter's Coffin

At a Hunterian dinner in 1847 Dean Buckland of Westminster, father of Frank Buckland, expressed regret that the medical profession had erected no monument to Hunter, and mentioned that he had himself suggested the propriety of such a monument in Westminster Abbey. Eleven years later Frank Buckland, then an assistant surgeon in the Second Life Guards, read an Order in Council requiring the vaults of St. Martin's to be cleared of their coffins, and, having confirmed the fact of Hunter's burial there, he set himself the macabre task of finding Hunter's coffin among more than 3,000 in the charnel house. It was the last but one exposed to view, and a few weeks later, in a gathering of more than 600 persons, the remains were re-

translator adhered. The origin and development of this school is briefly treated by Dr. Drabkin. We could wish that he had given far more space to a general discussion of these schools. The dominant philosophical element of the Methodist school was scepticism, but this attitude was sufficiently moderate to permit the formulation of certain principles, based on observation of individual cases. The doctrine of the Methodists was basically atomic. They held that the atoms moved about freely in "pores" in the bodily fabric. Disease was supposed by them to consist in changes in the pores, which were either abnormally stringent and narrow or, on the other hand, excessively relaxed. The Methodists repudiated the doctrine of the "Dogmatic" school that perversion or misplacement of the humours was the cause of disease—a doctrine which survived almost intact into the nineteenth century, had some place even in quite modern medicine, and has left its impress on current medical nomenclature. The work before us is the main source of our knowledge of the opposing Methodist school. Hence its historical importance.

The enormous text of Caelius Aurelianus, together with the excellent English translation that confronts it, occupies no fewer than a thousand pages of Dr. Drabkin's impressive volume. It would be impossible here even to sketch the contents. As knowledge is at present distributed, it must be regarded as an undertaking made for the sake of the small band of medico-historical specialists, but for them it is indispensable. It must suffice here to say that the presentation and scholarship displayed are all that could be desired. The work will become a *locus classicus* for all interested in ancient medicine, who will find it specially useful in tracing the origin and descent of medical terms. Professor Drabkin is to be both congratulated and thanked for his disinterested labours in adding an important reference book to the scholar's library. Only great foundations for learning, such as the Carnegie, the Guggenheim, or the Bollingen Foundation, who have supported this work, could have met the expense necessary for its beautiful production. Those responsible for these funds will have the satisfaction of having subsidized a permanent addition to learning, for which the writer of this review is himself personally grateful.

CHARLES SINGER.

Reports of Societies

DRUG RESISTANCE

A meeting of the Pathology Section of the Royal Society of Medicine was held at 1, Wimpole Street on February 5, when "The Drug Resistance of Micro-organisms" was the subject for discussion.

Professor L. P. GARROD opened the discussion with a survey of the subject. Resistance to drugs, first observed in trypanosomes, and now a most important problem in connexion with bacteria, was not confined to micro-organisms; it could be observed in populations of insects to agents such as dichlor-diphenyl-trichlorethane (D.D.T.) or even in human beings to narcotics. Such resistance was most commonly developed to drugs having a highly selective and subtle type of action, but some degree of resistance could be developed against even general protoplasmic poisons such as phenol. Penicillin resistance was seldom a problem except with staphylococci. Sulphonamide resistance was very often observed. Streptomycin resistance was very frequent and rapid in its development; it could reach a point where organisms were dependent on the drug for their continued growth. Cross-resistance occurred occasionally, particularly to the antibiotics most recently extracted from streptomycetes; strains of bacteria that had developed resistance to "aureomycin" were usually also resistant to "terramycin" and vice versa, and they were sometimes slightly resistant to chloramphenicol. Gram-negative bacilli were the worst offenders: the pyogenic cocci had much less capacity to become resistant to

the newer antibiotics. There was some evidence that when penicillinase-forming species acquired resistance to aureomycin they became more sensitive to penicillin, and in other cases "neomycin" treatment could in some way decrease resistance to aureomycin and terramycin.

Mechanism of Resistance

It was interesting to speculate on the possible mechanisms by which resistance could be acquired. There was evidence that organisms having innate drug resistance could become prevalent by strain selection: variations in sulphonamide sensitivity existed among strains of gonococci isolated before 1937 that could never have come into contact with the drug. In most instances the change occurred in a bacterial population which had previously been wholly sensitive. Whether such change in resistance was the result of cell adaptation or of mutation was a subject on which there had been much argument, and the issue had not been made clearer by the introduction of genetical dogma which was probably irrelevant when one was considering cells dividing by binary fission, since the daughter cells might be expected to have all the parental characteristics, whether hereditary or acquired.

Dr. E. F. GALE continued the discussion from the experimental point of view. The usual technique by which resistant organisms were produced and studied was by growing them in serial dilutions of the drug and selecting for further culture organisms that just survived the highest concentration. Usually resistance appeared in a series of jumps or steps, but occasionally complete resistance appeared in one step. Two such instances had been investigated: in the first, organisms had acquired complete resistance to penicillin in one step by developing an enzyme, penicillinase, which destroyed the drug before it ever came into contact with the organism; in the second, W. W. Umbreit had demonstrated a mechanism in bacteria whereby addition of oxaloacetic acid increased the ability of the organism to oxidize pyruvic acid; he ascribed this to a condensation reaction between the two, forming a cycle resembling the Krebs citric-acid cycle. Streptomycin prevented this condensation, but full resistance to streptomycin could be produced in one step presumably by by-passing this mechanism, which although essential to the normal strain was absent when it became resistant to streptomycin. Staphylococci usually became resistant to sulphonamides in four or five jumps; the largest jump was always associated with an increase in the production of *para*-aminobenzoic acid; another jump was associated with loss of ability to synthesize methionine. Similar jumps occurred in penicillin resistance, and in one of these groups the normal passage of amino-acids into the cell ceased. He himself had previously shown that one of the actions of penicillin on normal bacteria was to inhibit the uptake of amino-acids, and it was reasonable to infer that in acquiring resistance the organism became able to synthesize these substances for itself.

In reply to Professor Garrod, who asked how long the interruption of a metabolic process would take to kill a bacterial cell, Dr. Gale replied that studies with isotopes showed that ammonia nitrogen could become incorporated in the cell in as little as three minutes; if a process such as this were interrupted cell death would probably occur in a matter of minutes.

Effect of Bacterial Environment on Development of Resistance

Professor R. KNOX emphasized that in considering the resistance of micro-organisms to drugs or antibiotics it was necessary to distinguish clearly between enzyme adaptation and natural selection. He suggested that often a resistant mutant in a bacterial population might be selected out only if growth conditions were such that it could adaptively produce an essential enzyme. As an example, he quoted some work he and Dr. P. Collard were doing with a penicillinase-producing strain of *B. cereus*. In the absence of penicillin, the organism grew well in broth at 37° and 42° C. When grown at 37° C. in the presence of penicillin,

the organism appeared to be highly resistant. This resistance depended on its power to produce penicillinase. At 42° C. the organism was 10-100 times more sensitive, presumably because it could not adaptively produce penicillinase at that temperature. This example also showed the need for standardizing the conditions of growth in assessing the sensitivity of micro-organisms.

Preparations and Appliances

AN INTRODUCER FOR PLASTIC CANNULAE

Dr. J. V. MITCHELL, of the Nuffield Department of Anaesthetics, Oxford, writes: The advantage of using fine plastic tubing as an intravenous cannula is often lost through the difficulty experienced in its insertion. The introducer described here, however, allows tubing to be inserted as easily and as aseptically as an intravenous needle of a size similar to the selected tubing. It is prepared from the smallest aspirating needle which will admit the tubing into its lumen. For two-thirds of its length part of the wall is removed by grinding, leaving a U-shaped section bearing the point (Fig. 1). The needle mount is removed, being replaced by a holder (Fig. 1, A), which helps to control the shaft during introduc-

tion. The holder is slotted to prevent contamination of the tubing by the fingers. The end of the tubing is bevelled in the same plane as the point of the needle, near which it lies in the groove. A minute rubber ring holds the tubing in place during sterilization. An intravenous drip can be attached to the other end of the tubing, or a Gordh diaphragm on a needle, if intermittent injections are intended.

The bore of the tubing is increased to such a slight degree by the introducer that a vein on the dorsum of the hand is generally found convenient for the smallest size of tubing. The wrist is constricted and the vein further dilated by a flick of the finger. The skin is sterilized, and the shaft with the tubing in place is inserted into the vein (Fig. 2); the constriction is released and the tubing advanced into the vein. The introducer is then withdrawn (Fig. 3). A small dressing with strapping is applied to fix the tube in place. The largest polythene tubing has been inserted with equal ease into a suitable vein in the forearm.

My thanks are due to Mr. Richard Salt, of the Nuffield Department of Anaesthetics, who made the introducer for me.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

What Doctors Prescribe

SIR,—I have read with great interest the article by Professor D. M. Dunlop and colleagues on a survey of some prescriptions issued on Form E.C.10 during 1949 (February 9, p. 292) and also recent correspondence on prescribing habits and on changes in doctor-patient relationship. The following summary of a pilot investigation made last year seems to me to indicate the sort of information which is required in order to answer some of the questions which are being asked. I suggest that an extension of such studies is required and might well be organized on a wide scale.

The practice selected was a mixed industrial and country one in South Wales, worked by one man, the period five weeks in summer. A note was made after surgery of every relevant detail, copied from the N.H.S. record cards and supplemented while memory was fresh. Analysis of such records (my part of the task) can give only a glimpse of one part of one man's practice, but several interesting points emerge. From a list of approximately 2,800 patients no fewer than 640 (23%) consulted him during this "quiet" tenth of the year, making 976 visits to the surgery (average number of visits 1.72, duration six minutes) and being seen in their homes 129 times (average number of visits 1.8). Of these 976 consultations no fewer than 119 (12%) were made by proxy, and 34 in all (3.5%) were, after cool consideration, noted as unsatisfactory in that the patient had a contempt for the doctor rather than a desire for his help. The age and sex distribution of the patients was a close reflection of the local population distributions. Of the 640 patients 423 (66%) were considered to have something the matter with them physically and 68 (13.5%) mentally. Only 41 (6.4%) were sent to bed, 44 (6.9%) to out-patient departments, and 81 (12.6%) given treatment in the surgery. A partial or complete examination was made on 365 patients (64% of those visiting the surgery) and on all bed patients.

The pattern, therefore, is of steady, careful, time-consuming work additionally burdened by record-keeping, telephone, etc., and relieved by the daily round of visits. In winter the burden must be severe.

As to the prescriptions, 570 of these were issued (89% of patients), of which 489 (86%) were from the *N.F.*, 77 (13.4%) were proprietaries, and only four (0.7%) were "classical" scripts written by the doctor. This figure casts doubt, not on the capability of the physician to write a prescription, but on the need to devote much time to teaching the medical student how to write prescriptions. The number of proprietaries ordered would have been much less if the 1952 addendum to the *B.P.* 1948 had been official at that time (antihistamines). No fewer than 441 (78%) were for "bottles"—stomachics, cough mixtures, tonics, and liniments. Analysis of the scripts on the same lines as those in the article quoted gives the following results: tablets 33%, mixtures 30%, skin 10.6%, dressings 8.9%, liniments 5%, powders 3.9%, guttae and E.N.T. prescriptions 3.8%, and injections 2%. The greater proportion of powders recorded here than in the wider survey indicates the preference of the individual for *pulv. trisilicas* co. whenever possible, in face of some consumer resistance. The number of liniments (mostly terebinthinae) is indicative of local climate, housing, and employment (fibrositis and bruises). Of all *drugs* prescribed the frequency distribution of the main items was as follows: cough (mainly *linctus codeinae*) 18.8%, stomachic 13.2%, hypnotic (almost all barbiturate, a few chloral and bromide) 13%, antipyretic analgesics 6.6%, antihistaminics (half topical) 6.2%, tonics (*nux vomica*) 4.4%, spasmolytic, etc. (*ephedrine*) 3.4%, sulphonamide (half gutt. *sulphacetamid. mit.*) 3%, penicillin (half topical) 2.4%, cardiac 2.4% (no tincture of *digitalis*), analgesics 2.2%, iron, laxatives, and hormones (*stilboestrol*) 2% each, urinary 1.6%, amphetamine (slimming) and vitamins (C and D) 1.4% each.

Several points are worthy of comment. The high percentage of cough mixtures and of spasmolytics (*ephedrine* and *isoprenaline* for asthma) is indicative of mining practice. *Isoprenaline* inhalation is much preferred to *adrenaline* by injection and is often as effective. Tonics were still needed

in summer and were often demanded. Antihistaminics are being prescribed with great frequency for skin diseases. This phase will pass. Pethidine was preferred to morphine for many cases: amidone was not so successful. The relative infrequency of prescribing penicillin was partly due to lack of clear indications for the need of parenteral treatment in patients not sent to hospital and partly due to the technical trouble of such administrations. The infrequency of prescribing iron was due to the lack of clear indications for its use in the absence of a haemoglobinometer. How many practitioners use their haemoglobinometer regularly?—I am, etc.,

Department of Pharmacology,
Welsh National School of Medicine,
Cardiff.

J. D. P. GRAHAM.

SIR,—An F.R.C.P. from a department of therapeutics writing about general practice is rather like a naval gunnery expert from Hayling Island giving directions about the trawling of herrings: he knows a vast amount about nautical affairs, but perhaps has no actual experience of the matter in hand. And, although he is able to make many shrewd observations, his article must be salted with salt—a grain of salt will hardly suffice.

When I prescribe a proprietary drug it is usually because I cannot remember its pharmacopoeial equivalent—for example, "dexedrine" and "fersolate." Some proprietary drugs I consider better than their equivalent—for example, "salyrgan" than mersalyl. In my surgery I usually look up the equivalent, but cannot do so when visiting.

In practice, mixtures do give more satisfaction than tablets. Only to-day I visited a lady who had scalded her face and has now got a pain in her back; she told me aspirin does not agree with her but that I had given her some medicine three years ago which acted like a charm. I could not remember it, but on looking up my notes I see that the "magic" draught was mist. acid. acetylsalicyl. Would the department of therapeutics advise me to disclose my petty deception?

The same thing applies to powders; I find that a dose of alkali totally inadequate to neutralize the acid in the stomach, as Professor Maclean taught me, does in fact relieve symptoms (especially if belladonna and bromide be added) better than an adequate dose of powder. Am I to believe the patient or Maclean?

The reason for 12% of prescriptions being skin preparations is that something like 7% of one's patients come on account of skin complaints. I am often astonished at the amount of ointment people manage to consume on quite small areas.

I frankly admit that tonics are placebos. I always drink the samples sent me through the post and have never yet noticed any effect at all; if I am despondent, I am despondent still; if disagreeable, I am disagreeable still. One day I was shocked to see my small daughter drinking her medicine out of the bottle; it seemed lese-majesty. "Oh, but you always do, Daddy," she said—a fact that I had never noticed, expressing, I suppose, my subconscious opinions.

I agree that most of my cough medicines display "therapeutic confusion." Mist. morph. et ipecac. is my favourite (and my patients'). I can only plead that I didn't invent it, and had nothing to do with compiling the *National Formulary*. The British people spend £778m. per year on tobacco to give themselves coughs and peptic ulcers, but to tell patients that is like whistling to the wind. They don't come for advice; they come for medicine. "May one be pardoned and retain the offence?" That is their demand, and advice which even suggests using the will is always resented. All the same, being directly descended from Don Quixote, I never can refrain from giving it—plus medicine as well, of course, or I shouldn't have a practice at all.

When consultants write about colds in the head and the inadequacy of antiscorbutic vaccines I always wonder what experience they have and how they get it. The common cold has few objective signs except a pocket handkerchief

completely soaked by 10 a.m. Most people, and it would seem all consultants, are relatively immune, and it would not be worth while giving monthly injections to people who only have a couple of colds lasting three or four days each winter. But when you get a person who has a continuous series from September to April lasting two or three weeks each, with only a few days clear in between, you are called upon to make some effort at prevention. I was such a person, and in the wet autumn of 1917, when under canvas in France (ideal conditions for health, as we were being fattened up for Passchendaele), I had had about four colds by December. The same sort of thing happened in my student days and when I was first qualified, till I began inoculating myself with a well-known anti-catarhal vaccine in 1921, which immediately cut my colds down to two per winter—real soakers still, lasting three weeks. I continued with monthly injections from September to April year after year, till in 1949 I thought I might have acquired immunity, not having had a bad cold for about 10 years: that winter I escaped, but in 1950–1 I began my three-week soakers again. So now I am back on the vaccine, so far with complete success.

My policy with patients is to recommend vaccine to those who catch "one cold on the top of another," but not to people who have less than four per winter. In adults one may hope to cut down the number of colds in perhaps 50% of cases so selected—and in a much higher proportion in children, but injections are not popular with them.

When punching cards it might be well to remember that family doctors do see an undue proportion of feeble and timid folk: people who would consider as heartless or cruel any suggestion that courage, patience, or fortitude should be used as secondary armaments for combating disease. And I think that does account for, if it does not justify, the alarming number of hypnotics, sedatives, stomachics, and tonics prescribed.

The department of therapeutics must not forget that by cutting off G.P.s from the fellowship of the hospitals at an early age they do reduce the quality of their diagnosis. Hospitals have two functions: treating the sick and training students and keeping graduates up to date. The last of these is not seriously tackled at all. G.P.s don't need to be lectured at: they need to be an integral part of the hospital in the place where they live, with the day-to-day contacts that would give rise to.—I am, etc.,

Notwich.

FREWEN MOOR.

SIR,—I have read the Edinburgh prescription survey with considerable interest, and I feel that Professor D. M. Dunlop's searching paper into the prescription habits of medical men (February 9, p. 292) will appeal not only to teachers in medical schools but will prove of considerable value to all students of therapeutics and pharmacy and to any person interested in the historical development of modern medicine. Similar studies were conducted at frequent intervals by the American colleges of pharmacy, and it is hoped to inaugurate prescription studies on a similar basis in this country.

The practical value of individually conducted surveys would be greatly increased and misunderstandings avoided if all investigators were to establish a certain measure of uniformity in their methods of classification. Professor Dunlop and his associates state that the proportion of proprietaries in their sample was about 21%. Considering that the estimate published by the Ministry of Health for prescriptions dispensed during 1949 states that figure to be 16%, this difference is of statistical significance. Either the sample used by the Edinburgh survey is not representative of medical prescribing habits, or the term proprietary is defined differently in both studies. A comparison of Professor Dunlop's figures with those of the Ministry seems to suggest that the Edinburgh survey classifies the various brands of insulin and penicillin preparations as proprietaries, while these products were excluded from the definition of proprietary preparations in the official estimate.

I was told only a few days ago by a person with a strong political bias that the medical profession "was trying to undermine the Health Service by recklessly prescribing proprietaries. In support of this argument official statistics were quoted: the proportion of proprietaries prescribed had increased from 16 to nearly 40% during the last two years. Intentionally or unintentionally my informant failed to stress that the latter figure relates to the total cost and not to the total number of N.H.S. prescriptions. I always feel that if people are discussing highly controversial matters they may just as well know what they are talking about.—I am, etc.,

Pinner.

H. W. TOMSKI.

SIR.—Professor D. M. Dunlop and his associates (February 9, p. 292) complain that iron is prescribed less frequently than vitamins. Surely there is good authority for prescribing vitamin C whenever iron is given, so that one would expect the total prescribing of the vitamins generally to be greater than iron, and not less as they suggest.

Also many people who have tried a simple iron preparation such as Bland's pill and an iron pill combined with folic acid notice that the latter group seem to respond more rapidly. As for "enormous quantities of wool and lint," surely hospitals sending patients with, say, a colostomy home before they have been fitted with a colostomy belt bear some responsibility. And the G.P. might reply to the, what seems to me, irrelevant plaint, that candidates for "a higher examination" did not know how to combine cascara and belladonna in a pill, by pointing out that the public seems to buy more of the pills which contain phenolphthalein, which does not need an antispasmodic of the belladonna group to be added, and cascara is "old fashioned."

Finally, the vasodilators, which are rarely used in September, are more popular in winter.—I am, etc.,

Manchester.

S. SHUBSACHS.

Coal and Cortisone

SIR.—Dr. Ffrangcon Roberts starts his article (February 9, p. 321) with a preamble concerned to justify cuts in the Health Service. His arguments in this preamble are completely invalid, and I hope the medical profession will decisively reject the ridiculous conclusion that we cannot afford good health.

The figures quoted by Dr. Roberts show that with an ageing population the number of dependants per worker is increasing at a rate of a little over $\frac{1}{2}\%$ per annum. On these grounds alone we are told it will be necessary to put proportionately more and more workers into industry to produce the necessities of life, and consequently proportionately less and less workers into medicine (and presumably all other social and cultural activity not directly concerned with industrial production).

If Dr. Roberts had cared to quote the Government Index he could equally well have shown that in recent years the productivity of each worker increased by about 7% per annum. There is no reason to doubt that technical improvement could continue such increases indefinitely. Hence if those who control our economic destiny were so minded they could gear our resources to ever-improving social services without worrying over-much about the ageing population.

Dr. Roberts has, I hope unwittingly, attempted to present as economically inevitable what is in fact a deliberate choice: "Guns before Butter."—I am, etc.,

Brighton.

R. S. SAXTON.

A Forgotten Tourniquet

SIR.—With reference to the letters of Drs. C. F. Hadfield and John Ives (February 9, p. 328), please allow a mere physician to pose a question: Has it ceased to be the invariable rule for the tourniquet to be removed before the wound is closed, in order that complete haemostasis may be secured?—I am, etc.,

Downton, Wilts.

J. C. MATTHEWS.

Paying for the Health Service

SIR.—I am indebted to Mr. H. A. Marquand (February 2, p. 272) for drawing attention to an error in my article (January 19, p. 129) and for emphasizing the fact that only one-twelfth of the money spent on the National Health Service came as a grant from the Insurance Fund. May I be permitted to point out that I did mention taxation as a means of financing the Service? Indeed, in common with my colleagues, I am unlikely to underestimate the importance of taxation in this respect. My object in writing, however, is to repudiate any suggestion that, indirectly or otherwise, I countenance extravagant use of the Health Service.

My only reason for mentioning the finance of the Service was to emphasize that, as the cost of it is now borne at a national level, there is no longer any reason for regional inequalities in the provision of hospital facilities, and that the policy of "fair shares for all" should operate within the Health Service as much as in any other field of social welfare. I think that the bed/population ratios cited in Table II of my article make it apparent that, at any rate in the Birmingham Region, there are considerable differences in available hospital facilities in the various localities. There is, I believe, reason to suppose that such differences exist also in other regions. My contention is, therefore, that it behoves the Ministry of Health to concentrate first on the provision of adequate hospital facilities in those areas in which at present these are deficient.—I am, etc.,

London, S.E.5.

VERA NORRIS.

Sexual Disorders in Women

SIR.—I am sure that Dr. P. R. Boucher is correct in his observation (February 2, p. 273) that some women have their erotic sensation limited to the cervix. They seem, however, to be in only a small minority, and I would question his explanation for any inabilities they experience in attaining orgasm. Personally, I think that incomplete penetration is far more likely to be a cause, for this is a factor very commonly present in unsatisfactory coitus and is particularly distressing to women of this sort.

The extended posture, so commonly adopted for coitus, causes the cervix to be quite inaccessible in some women. It also exaggerates any tendency to introital spasm, thus increasing cervical inaccessibility still more. In all quadrupeds the female accepts coitus with her knees to her flanks, and in this position the vagina not only relaxes, but it shortens so that the cervix is properly contacted for insemination.

I agree with Dr. Boucher that a woman with erotic sensation restricted to the cervix may have her orgasm ability lessened by the presence of an occlusive cap: but fortunately the condition is uncommon and presents no serious problem in contraceptive work. More often it is the urethral area—i.e., the anterior and lower third—of the vagina which is the site of a purely limited eroticism. Although these conditions are rare, they should be borne in mind when advising women about sexual difficulties.—I am, etc.,

London, N.W.1.

JOAN MALLESON.

Antistix in Habitual Abortion

SIR.—In view of the successful prophylaxis of habitual abortion by means of progesterone implants reported by Dr. P. M. F. Bishop and Dr. N. A. Richards (February 2, p. 244), it is interesting that L. Hirsfeld (*Méd. et Hyg.*, 1950, 8, 299; *Schweiz. Z. allg. Path.*, 1951, 2, 133) has had encouraging results from the use of antistix, both in abortion (habitual and other) and hyperemesis gravidarum. Hirsfeld's allergic interpretation of these conditions is based on his finding, in abortion, of a significant excess of the matings of Rh-negative husband x Rh-positive wife and Rh-positive husband x Rh-negative wife, without any anti-Hr or anti-Rh agglutinins in the maternal circulation.—I am, etc.,

Aberdeen.

T. M. ALLAN.

Intra-parium Uterine Rupture

SIR,—I read with interest the medical memorandum by Mr. Robert Hodgkinson (February 9, p. 308), but I was very disturbed by his opening paragraph stating that rupture in the lower segment was more dangerous than in the upper segment. It is true that at first I had misinterpreted what Mr. Hodgkinson meant, for I thought he was comparing upper with lower segment rupture of a previous caesarean scar. Moreover, his summary of Dugger's work confirmed the misapprehension (actually only the 34 cases in that series were following a previous caesarean section, and the paper does not say that they were classical operations—although they probably were—the remaining 71 were all traumatic or spontaneous). Actually I have since learnt by personal communication with Mr. Hodgkinson that he does not think there is much to choose between a lower segment rupture following a caesarean section or that occurring as a spontaneous or traumatic event. It is over this that I wish to take up the cudgels. I agree with him entirely over the danger of the spontaneous or traumatic tear going out into the parametrium and involving the uterine vessels. I have seen two such cases, and very ill they were. But the rupture of the lower segment scar, a rare event, is usually a far less dangerous matter. For evidence to support this statement, I would refer Mr. Hodgkinson to a paper read by Dr. Dewhurst and Dr. Rowley before the North of England Obstetrical and Gynaecological Society in January, 1951 (*J. Obstet. Gynaec. Brit. Emp.*, 1951, 58, 630). Two cases of "silent" rupture of the lower segment scar are described. I have seen a third: a live mother and a live baby were obtained in each case. These cases present like an over-distended bladder due to the unruptured membranes bulging through the uterine defect, and at operation little bleeding is found from the fibrotic margins of the tear. From their own cases and from a study of 66 cases in the literature, Drs. Dewhurst and Rowley conclude that "more time is probably available for diagnosis and treatment whilst the general condition of the mother is still good and the child is alive" than is the case with rupture of a classical caesarean section scar. It is true that some cases were mentioned where damage to the bladder occurred following rupture after the lower segment operation, but I feel that the evidence is sufficient to justify regarding rupture of the lower segment following a previous caesarean section as likely to be a far less dangerous matter than a spontaneous or traumatic tear, and, of course, less dangerous than rupture of a previous classical caesarean section scar. No doubt there will be exceptions, and it would be instructive to hear of them.—I am, etc.,

Bristol.

T. F. REDMAN.

Ferrous Sulphate Poisoning in Children

SIR,—Having in the last few days had the supervision of a case of ferrous sulphate poisoning, I am disposed to comment upon Dr. I. O. B. Spencer's excellent paper (November 10, 1951, p. 1112). In it the emphasis was laid on the damage to the central nervous system which is said to occur, in contradiction to the older view that liver damage is the most important feature of these cases. After seeing one fatal case in which the extent of damage to the liver was almost comparable with acute yellow atrophy, I am convinced of the need to protect the liver so far as possible. Since the severe gastritis makes oral feeding not only inadvisable but impracticable for the first 24 hours or more, there would seem to be theoretical advantages in giving intravenous glucose and amino-acids from the start. Vitamin-B complex for intravenous use can be added to the infusion. In the case which is summarized below it was noted that the liver enlarged considerably after 24 hours and became very tender, returning to its normal size after two days.

A boy aged 4 years was admitted at 3.30 p.m. on January 4 with haematemesis and diarrhoea. He was known to have swallowed

at least 20 ferrous sulphate tablets some four hours previously. On admission he was mildly shocked, with pallor, coldness of extremities, and a rapid pulse. His state varied from drowsiness to extreme irritability. There were frequent small vomits streaked with blood during the first hour after admission, and he passed three large watery stools. Clinically, there was no dehydration, and there were no abnormal signs in the central nervous system. An intravenous infusion was commenced using casein hydrolysate in 5% dextrose to which an ampoule of B complex for intravenous use (Roche) had been added. He was given two pints (1.2 l.) of this solution in 24 hours. The following day his general condition was improved, but it was found that his liver was enlarged to two fingerbreadths below the costal margin and was very tender. Diarrhoea with tarry motions continued. By the third day he was greatly improved and able to tolerate his diet. The liver had now returned to its normal size. Liver-function tests showed no gross abnormality and he was discharged well on the seventh day.

In a boy of 4 years it is reasonable to suppose that 20 tablets of ferrous sulphate would not prove fatal. However, it seemed to be our duty to try to protect the liver. We should have done better, perhaps, to have fortified the casein hydrolysate with methionine.

One other point: many of the early symptoms of ferrous sulphate poisoning, such as tachycardia, drowsiness, shallow respirations, and mental confusion, are reminiscent of alkalosis, a state which could result from the excessive vomiting. It might be a wise precaution, therefore, to estimate the CO_2 -combining power, since we are advised to wash out the stomach with sodium bicarbonate, leaving 10 oz. (285 ml.) of the solution in the stomach, and then follow with bismuth carbonate, 3 gr. four-hourly.—I am, etc.,

Cardiff.

R. J. K. BROWN.

Splenins A and B in Rheumatoid Arthritis

SIR,—With reference to Dr. Raymond Greene's paper on rheumatoid arthritis and bleeding time (January 5, p. 17), we have carried out a number of tests of this type at the Royal National Hospital for Rheumatic Diseases. Our mean bleeding time for normal guinea-pigs was 97 seconds (S.D. ± 26 seconds, $n=95$). When "splenin A" and "splenin B" extracts from 11 cases of rheumatoid arthritis were injected into guinea-pigs, 80 bleeding-time values for A gave a mean of 124 seconds ± 17 , and for B 201 ± 58 . Similarly prepared extracts from normal sera gave an A-time of 114 and a B-time of 80 seconds. These figures do not invalidate the claim that an acetone-soluble substance (splenin B) increasing the bleeding time of guinea-pigs can be obtained from the blood of rheumatoid-arthritis cases.

One case of rheumatoid arthritis was investigated in this way before and after splenectomy. Guinea-pigs injected with extracts of the patient's serum before splenectomy gave an average A-time of 119 (S.D. ± 30 , $n=24$) and B-time of 125 (S.D. ± 39 , $n=24$). After splenectomy 19 such experiments with the patient's serum resulted in a mean A-time of 99 ± 20 and B-time of 77 ± 23 —presumably indicating an absence of B factor, as might be expected from Ungar's theories.

We feel that the guinea-pig bleeding method is so fraught with fallacies that these results should not be taken too seriously, although they support to some extent Ungar's figures. Other methods of investigating this problem are under consideration.—We are, etc.,

Thumping the Chest

SIR,—Two patients encountered recently interrupted their swallow of a thick barium mixture to thump their upper chests with impressive vigour. Both patients suffered from achalasia of the cardia. The disease was at an early stage and only moderate dilatation of the oesophagus was present. The notable feature was a depression of normal peristaltic activity, and barium aggregates formed along the walls of

A new antibacterial

for topical application

'FURACIN' SOLUBLE DRESSING has advantages over previous anti-microbial therapy. Its wide antibacterial spectrum includes gram-negative as well as gram-positive organisms; healing rate is not retarded; wound odour is diminished; and the occurrence of bacterial drug-resistance has not been reported.

'Furacin' Soluble Dressing is useful for topical application in the prophylaxis and treatment of surface infections occurring in wounds, burns, or ulcers.

These advantages over other antibacterials are possessed

also by 'Furacin' Solution which presents the active principle — 'Furacin' — in a liquid vehicle.

Both preparations contain 0.2% nitrofurazone.

'Furacin' Soluble Dressing is available

in 2-oz. tubes, 4-oz. and 16-oz. jars.

'Furacin' Solution is available in 2 fl. oz.,

4 fl. oz., and 16 fl. oz. bottles.

Further information on request

The outlook need not be clouded ..

... by the shadowy fear of the menopause and its associated vasomotor and psychic disturbances.

Euvalerol M, the ideal sedative in menopausal conditions, ensures that the difficult years may be contemplated with equanimity and passed through with ease.

Symptoms of apprehension, flushing, irritability and depression that darken the outlook of the woman at the menopause are alleviated, and the emotional balance restored, by the administration of Euvalerol M.

Euvalerol M contains an odourless preparation of valerian with $\frac{1}{4}$ grain (16 mg.) phenobarbitone and 0.1 mg. stilboestrol in each fluid drachm.

EUVALEROL M

In bottles of 4 and 8 fluid ounces.

the upper oesophagus and persisted at these positions for periods varying from one to three minutes. The manoeuvre of thumping the sternum was immediately effective in dislodging these clumps and in causing the barium to fall to the lower oesophagus. In one case pain accompanied the barium swallow, and this was promptly relieved by the thumping. The other patient felt occasional pain on swallowing, and at one time when this was severe he had obtained relief by asking his wife to thump his back. The explanation would appear to be that the food or barium causes direct mechanical irritation of sensitive areas of the oesophagus which are the site of hyperaemia or superficial ulceration.

Barium aggregates along the oesophageal walls are not common in conditions other than achalasia, and this may explain why thumping is so effective and has been met with in this condition alone. Patients thump their chests for a variety of reasons, and these range from a feeling of well-being to the first-aid treatment of food that has gone the wrong way, and such a symptom will be difficult to interpret. In combination with dysphagia, however, a history of thumping of the sternum during swallowing may suggest the diagnosis of achalasia of the cardia. It would be useful to know if the manoeuvre has been encountered by others and in conditions other than achalasia.—I am, etc.,

Cardiff.

BRYAN WILLIAMS.

Infective Gangrene of the Mouth

SIR,—At the Royal Society of Tropical Medicine on December 13, 1951, Dr. D. B. Jelliffe spoke of a form of infective gangrene of the mouth which differs from cancrum oris since it infects the bones (January 26, p. 198). The condition described by Dr. Jelliffe resembles malignant granuloma of the nose, described by R. Woods (*British Medical Journal*, 1921, 2, 65) and again by S. W. G. Hargrove, J. H. Fodden, and A. J. Rhodes (*Lancet*, 1946, 2, 596), who stated that about a dozen cases had been described. Hargrove *et al.* treated their patient with penicillin, which improved the local lesion, but the patient died. Most authors state that the cause of malignant granuloma is unknown. I think the cause may be linked up with cutaneous gangrene (*Lancet*, 1945, 1, 739, and 1946, 2, 769). Bony changes associated with tropical ulcer were described by J. A. Brocklebank (*Brit. J. Radiol.*, 1943, 16, 221). There is an account, from the Mayo Clinic, of spreading osteomyelitis of the cranial bones (*Proc. Mayo Clin.*, 1944, 19, 480). The Mayo Clinic work was based on a paper by H. L. Williams and F. R. Heilman (*Arch. Otolaryng.*, Chicago, 1937, 25, 196) that a micro-aerophilic short-chained streptococcus is responsible for the malignant type of osteomyelitis. The Mayo Clinic workers found this organism sensitive to penicillin. Meleney recommended a special active preparation of zinc peroxide; I have found powdered potassium permanganate effective.—I am, etc.,

Epping.

FRANK MARSH.

Incontinentia Pigmenti

SIR,—The article by Dr. A. White Franklin on this subject (January 12, p. 75) prompts me to record a further case recently shown, together with her sister, by Dr. C. D. Calnan at the Dermatological Section of the Royal Society of Medicine (December 15, 1951).

A woman, aged 36 years, and pregnant for the sixth time, was delivered normally of a live female infant weighing 7 lb. 6 oz. (3.3 kg.) on July 30. On the second day of life "several small spots" were noticed and the following day the infant was thought to be suffering from pemphigus neonatorum and was isolated and treated with oral penicillin.

On August 3 the rash was described as a generalized herpetiform eruption, avoiding the palms and soles and confluent on the trunk. There were patches of erythema on the scalp and parts of the back, and the individual lesion was a small vesicle containing golden-yellow material. Culture of the latter was sterile on 48 hours' incubation. By August 5 the rash was clearing off the face and trunk but was confluent and shotty on the lower limbs, while on August 7 the lesions were noticed to

be coalescing on the lower limbs and trunk to form subcutaneous plaques. No marked pigmentation was noticed, and throughout the temperature remained normal and the baby's general condition was excellent. Owing to family problems, the mother took her own and her baby's discharge on August 8 and was advised to attend the Hospital for Sick Children, where the diagnosis of incontinentia pigmenti was made.

In 1947 she had been delivered of a female infant, weighing 8 lb. 8 oz. (3.9 kg.), and this baby, too, had developed a skin rash in the neonatal period. Inquiry revealed that this child had incontinentia pigmenti. It is interesting to note that the mother of these two children had been blind in her left eye since childhood, but this was caused by a post-traumatic cataract.

Both these infants were female; neither was premature.

My thanks are due to Mr. R. M. Millen for permission to publish this case and for his helpful criticism, and to Dr. Calnan for his kind help and advice.

—I am, etc.,

Clapton, E.S.

F. TAYLOR.

Unsuitable Advice

SIR,—I should be glad if you could find space to publish the following communication addressed to the Secretary of State, War Office, in the interests of the medical and dental practitioners who are serving with the Forces of the Crown. It is strongly urged that medical and dental officers should not terminate their membership of their defence bodies when by doing so they would deprive themselves of an independent medico-legal service which is essential for their individual protection.

"Sir,

"Our attention has been drawn to a Memorandum issuing from the War Office dated January 4, 1952, reference 24/GEN/3172 (AMD.1), denying the need for medical officers of the R.A.M.C. and dental officers of the R.A.D.C. to be members of a defence body.

"We are surprised by the definitive statement of the Director-General in that document that 'it is not considered necessary for R.A.M.C. medical officers or R.A.D.C. dental officers to join a medical or dental protection society in connexion with any treatment, etc., given in the course of their military duties.' This *ipse dixit* is linked to an assurance by a significant proviso—viz., 'If a medical or dental officer is sued as a result of his professional services whilst acting in the performance of his military duties the War Department will stand behind him provided that he signs a form of retainer appointing the Treasury Solicitor to act for him. The cost of any resultant settlement of the claim would then be met from Army funds and no financial liability in connexion with the settlement of the claim would fall upon the medical or dental officer concerned.'

"It is, however, more than surprising that the above advice was tendered to officers of the medical and dental services without giving the defence bodies, of which there are three in the United Kingdom, an opportunity of learning in advance the views of the Director-General and of contributing any constructive criticism they might desire to submit on the subject-matter of the Memorandum. To disregard these long-established professional organizations with a total membership of doctors and dentists amounting to 69,500 is to act discourteously.

"Without fear of contradiction, it can be said that the Treasury Solicitor and the Army funds at his disposal will not resolve satisfactorily a diversity of medico-legal situations by which an officer may be confronted and on which the document is peculiarly silent.

"We respectfully submit the following for consideration:

"1. There are occasions we could postulate from our long experience of medico-legal matters when the views that we might entertain for the protection of a medical or dental officer, or for the maintenance of an important principle affecting the profession as a whole, would be diametrically opposed to those held by the solicitor acting for the employing authority of the officer concerned. The interests of a doctor or a dentist do not always run parallel with those of his employer—often they are in conflict. The Treasury Solicitor, for example, may advise settlement of a case out of court when we feel that it should be fought through the courts to support the interests of the officer concerned. The Treasury Solicitor may think that an officer has been negligent in the conduct of his professional work when we think otherwise.

"Medical defence bodies are primarily concerned with defending practitioners whenever it is practicable to do so and of settling cases when the defence is unlikely to succeed. The Treasury Solicitor may have other interests to consider than those of the officer concerned.

"2. A medical or dental officer may require assistance with respect to court-martial proceedings. He may appear at these proceedings in several capacities; as one accused, as prisoner's friend, or as a medical witness; he may stand gravely in need of legal advice or legal representation for his own protection, and this may be of a costly order. (In a recent case £15,000 was spent in the defence of a medical officer.) Surely in the foregoing circumstances the Treasury Solicitor would be unwilling or indeed unable to furnish advice or provide representation.

"3. A medical or dental officer may find himself in acute disagreement with his employing authority with regard to his care and treatment of a military or civil patient, or with regard to the terms and conditions of his service, affecting rank, remuneration, or pension. He may be accused of libel or slander, or of some other civil or criminal offence arising out of or associated with the pursuit of his professional work. He may be called upon to appear at a military inquiry, a civil court, or the General Medical Council, and would need expert assistance to examine, prepare, and proffer a defence or a plea in mitigation and to avoid, if possible, detriment to his future in the Service.

"These situations demonstrate the necessity for the officer concerned to be able to resort to an independent defence body for appropriate personal help when necessary, and to assert, as is done in the Memorandum, that he could disregard the need for membership of a medical defence organization in the circumstances described therein is but to induce a sense of false security in the mind of an officer reading that document and to give advice that is incomplete and misleading.

"Though it is regrettable to disagree in public with the Director-General on a matter affecting medical and dental officers, it is clearly my bounden duty, as secretary of the body I serve, to warn these practitioners of the inadequate nature of the protection proffered in the Memorandum quoted above and of the continued need for them to maintain throughout their professional careers their membership of a defence organization to secure the availability of independent advice, legal representation, and financial indemnification when required.

"In view of the action already taken and about to be taken I have no alternative but to arrange for the early publication of this letter in the professional press."

—I am, etc.,

The Medical Defence Union,
London, W.C.1.

ROBERT FORBES,
Secretary.

Action of Different Insulins

SIR,—The search for a type of insulin which will give a more constant control of blood sugar levels in diabetes continues, and Dr. F. Gerritzen's interesting article (February 2, p. 249) gives examples of the duration of action in 10 different types of insulin used on normal persons. Those who are interested in the treatment of diabetes are glad to have any information on new varieties of insulin even if some of them are, for commercial reasons, not in general use in this country.

With regard to the insulins which are available here, I suggest it might be unwise to assume that a similar action to that described in the article mentioned necessarily applies in diabetes owing to a greater fluctuation in the levels of blood sugar and to the greater variation in sensitivity in diabetics as compared with normal persons.

As many diabetics are more afraid of hypoglycaemic attacks than of diabetes itself, the assumption that the action of protamine zinc insulin begins to wane after eight hours and is complete by 16 hours might lead to more nocturnal attacks, due to falling blood sugar, than are already encountered. It would also be useful to know whether the mixed insulins were given in the standard English way or in the American fashion—that is, a complete mixing giving rise to a fixed amount of soluble remaining in the mixture.—I am, etc.,

Warrington.

R. GUEST GORNALL.

Polycentron

SIR,—Recently I published a paper (Chrysanthis, 1948) on the comparative value of the two classical methods of vaccination, the multiple-pressure method and the standard scratch one, expressing myself in favour of a combined method of vaccination. But many authors, as Dunley and May (1932), Parish (1944), Mole (1947), and Lovett (1947),

find the multiple-pressure method more ideal. However, when applying the multiple-pressure technique I observed that it is rather more tiresome than the scratch one, especially when vaccinating a great number of people. In order to lessen this disadvantage of multiple-pressure technique of vaccination I invented an instrument, the "polycentron."

This (see Fig.) consists of two parts: a wooden handle of 5 cm. length, and a hard steel stalk of 3.5 cm. length, which fits into a block 1 cm. long and diameter 0.7×0.7 cm. The

lower surface of the block has 16 spikes, each of them protruding 0.15 cm. The vaccinator, after cleaning the skin, places a drop of calf lymph on the skin and presses the polycentron on it once or twice. So the vaccinator makes only one or two pressures, instead of 30-40 pressures with a needle as is required by the standard multiple-pressure technique of vaccination. The shortening in required time is obvious. This is more important when vaccinating a great number of people, as in schools and in the Army.—I am, etc.,

Habitual Abortion

SIR,—I read with great interest the article by Drs. P. M. F. Bishop and N. A. Richards on habitual abortion (February 2, p. 244) and appreciate their remarks about my own series of cases. From my own results two interpretations are possible: that the usually accepted spontaneous cure rate after three or more abortions is wrong; or that the treatment these patients received was sufficient to alter the foetal survival rate. I am reluctant to accept the first hypothesis, but am sure that the medicinal treatment patients received was insufficient materially to affect their chances.

I am not a great believer in the effect of psychology on organic disease, but am prepared to accept the fact that the emotions such as fear and anxiety can alter menstruation, presumably by action on the pituitary. The logical thing to do is to give these patients no treatment whatever, and this is being done by one of my colleagues.

I await with great interest the results of a series of patients treated by Drs. Bishop and Richards with the implantation of inert tablets.—I am, etc.,

Manchester.

D. C. A. BEVIS.

Thank You

SIR,—I am writing this short letter to thank those members of the medical profession who subscribe so generously to the funds of the Royal Medical Benevolent Society, thus enabling that organization to distribute regular pensions and welcome Christmas cheques to doctors who have to contend with ill-health and subsequent poverty. This short note is brief indeed, but it expresses the maximum of gratitude.—I am, etc.,

RECIPIENT.

POINTS FROM LETTERS

Succinylcholine Chloride

Dr. R. BLAIR GOULD (London, W.1) writes: In the literature accompanying this product occurs the following statement: "In the dose recommended . . . it produces a paralysis which lasts for about three minutes. Spontaneous respiration then returns. . . ." Since apnoea lasting 20-40 minutes is not uncommon after this drug, it would appear that the statement should be accepted with considerable caution.

Obituary

H. D. DAKIN, D.Sc., F.R.S.

Dr. Henry Drysdale Dakin, whose name is perpetuated by the hypochlorite solution he brought into use during the first world war, died at Scarborough-on-Hudson, New York, on February 10. He was born in London on March 12, 1880, the son of a Leeds iron and steel merchant. From the Leeds Modern School he went on, after a period of apprenticeship with the Leeds city analyst, to the Yorkshire College (now Leeds University), where he won an 1851 Exhibition Scholarship. It was about this time that he decided to take up the study of biochemistry, and from Leeds University, where he took the degree of D.Sc. in 1909, he moved on first to the Lister Institute and then to Heidelberg. In 1905 he went to the Herter Laboratory in New York, and thus began his long and distinguished career as a medical research worker in the U.S.A. Many honours came his way. He was elected a Fellow of the Royal Society in 1917, and the universities of Heidelberg, Leeds, and Yale conferred on him honorary degrees. In 1941 he received the Davy Medal of the Royal Society for his pioneer work in biochemical research, and for his contribution to the study of intermediary metabolism.

We are indebted to Sir Charles Harington for the following appreciation of Dakin's contribution to medical science: By the death at the age of 71 of Dr. H. D. Dakin, following closely on that of the late Professor H. S. Raper, biochemistry has lost another of the remarkable group of men trained under the late J. B. Cohen, of Leeds, who have done so much for the development of the subject in many different directions.

Dakin's early interest in biochemistry was aroused by a period of work with Kossel, during which the enzyme arginase was discovered. At the Lister Institute, where he worked for a few years, he made another important contribution in being the first to demonstrate the stereochemical specificity of enzymes in his study of the action of esterases on the esters of the active mandelic acids. During his time at the Lister Institute Dakin also published a synthesis of adrenaline.

In the early years of the present century Dakin went to New York to work in the laboratory of the late Christian A. Herter (whose widow he subsequently married). Here he soon became deeply involved in the researches for which he will always be best known—namely, the study of the intermediary metabolism of amino-acids and fatty acids. In this field, at that time practically unexplored, he made great contributions, on which much modern knowledge rests. His attack on the problem of fatty acid oxidation was made in parallel with that of Knoop in Germany; the result of the two investigations was to establish the nature of the process (β -oxidation) by which fatty acids are utilized in the animal body, and Dakin made the important observation that this process, as well as other biological oxidations, could be imitated *in vitro* by the use of hydrogen peroxide. Later, also in Herter's laboratory, Dakin returned to work on enzymes, and, in collaboration with the late H. W. Dudley, discovered and studied the properties of the enzyme glyoxalase.

During the 1914–1918 war Dakin worked on this side of the Atlantic, both in this country and in France. His

main contribution was the development of the buffered hypochlorite solution which became known by his name, and which found important application in the irrigation of infected wounds.

Apart from his work on enzymes and biological oxidations, Dakin's main scientific interest was in the chemistry of proteins and amino-acids, and it was to this subject that he devoted himself when he established his private laboratory at Scarborough-on-Hudson on his return to the United States after the war. His discovery of the racemizing effect of alkali on proteins enabled him to expose features of protein structure which at that time could not be revealed by other means. He also introduced new methods of separating amino-acids which made possible the more accurate determination of the composition of proteins. Although Dakin's methods have been rendered obsolete by the great advances in this field in recent years, his were pioneering studies in a subject that has proved to be of the greatest importance for biology.

Having much of the artist in his temperament, Dakin was essentially a lone worker. During the whole of his career he had few collaborators and he trained no pupils. Indeed, his only sustained collaboration was with H. W. Dudley, and this was based on close personal friendship as well as on community of scientific interest. Nevertheless any assessment of Dakin's contribution must take account not only of his personal scientific achievements, great as these were, but also of the very considerable influence that he exercised, in ways that did not appear on the surface, through his friendships with scientific colleagues. This influence and his own work combine to give him an outstanding place among those responsible for the development of modern biochemistry.

E. BRIGHT VEDDER, M.D., D.Sc.

Colonel Edward Bright Vedder, a distinguished United States Army medical officer, died in the Walter Reed Memorial Hospital, Washington, on January 30, at the age of 73.

He was born in New York and received his medical education at the University of Pennsylvania medical school, where he graduated M.D. in 1902. For a short time after this he collaborated with Simon Flexner, who was then studying the aetiology of bacillary dysentery. Vedder was commissioned in the Army in 1903, and participated in early typhoid immunization experiments. During later service in the Philippines he studied beriberi and found it to be associated with the eating of polished rice. It was as a result of this observation that he introduced the successful measure of substituting half-polished rice to supply the dietary deficiency, later found to be vitamin B₁. His monograph on beriberi (1913) won for him the Cartwright Prize of the College of Physicians and Surgeons of Columbia University. His work on clinical scurvy also led the way to further discoveries. In 1932 he was awarded the Wellcome Prize for his *Study of the Antiscorbutic Vitamin*. He also made important contributions to the knowledge on sprue, leprosy, and syphilis. In 1911 his demonstration of the amoebicidal action of emetine led to its general adoption in the treatment of amoebic dysentery. From 1922 to 1925 Vedder was chief of the medical research division at Edgewood Arsenal, and senior member of the U.S. Army Board of Research from 1925 to 1928. In 1930 he was appointed director of the Army Medical

School at Edgewood. He retired from the Army in 1933 and spent the next ten years as professor of pathology and experimental medicine at George Washington University.

Dr. WILLIAM DONALD MACKINNON, district medical officer at Portree, Isle of Skye, died suddenly on January 12, aged 59. He was a son of the late Reverend D. Mackinnon, who was at one time minister at Wanlohead, Dumfries. From Herriots School he went on to Edinburgh University, where he had a distinguished career as a student. He gained a first-class certificate for almost every class and no less than eight medals. After graduating M.B., Ch.B. with distinction in 1917, he joined the R.A.M.C. and saw service in France. After demobilization he held a number of hospital posts, including that of senior assistant and deputy superintendent of the Southern General Hospital, Glasgow. He there met his future wife, Dr. Mary MacDonald, who was his colleague on the staff. In 1922 he was appointed medical officer to the parish of Strath, in Skye. Strath was the traditional home of the Mackinnons, and that for him was one of the attractions of the post. In what now appear to be far-off days he almost always wore a kilt of his clan tartan. While in Strath he was superintendent of the Mackinnon Memorial Cottage Hospital, and he did some emergency surgery there. Two years later he went to the neighbouring parish of Portree, where he also had charge of the Skye District Infectious Diseases Hospital. In the British Medical Association he held office as secretary of the Islands Division from 1926 to 1939, and he was president of the Northern Counties of Scotland Branch from 1937 to 1938. He also served for many years on the Inverness county panel committee. A keen freemason, he was a member of several Chapters, including the Inverness Sovereign Chapter and Past Master of two lodges.

A.L. writes: Although his health had not been good for a number of years, the sudden death of Dr. W. D. Mackinnon came as a sad shock to his many friends. It was almost as if it required his death to make them realize how deep was their affection for him. Those who knew him only during the last few years can have had little idea of the liveliness of his intelligence or the catholicity of his mind in days gone by. It is possible that if he had followed hospital rather than general practice he would have more fully fulfilled his youthful academic promise. He could with ease have passed any examination he set his mind to, but he was entirely devoid of vulgar ambition. During the last few years he was dogged by illness, but, like other difficulties, he took it in his stride and made light of it. It was never an excuse, not to see a patient nor to attend a meeting. He was devastatingly frank and honest and assumed the same qualities in all with whom he had dealings. There might not always be universal agreement with him, but no one doubted his sincerity. His home, for which much credit must go to his wife, was a centre of hospitality for many people, both medical and lay. Much sympathy goes out to Dr. Mary Mackinnon, who did what she could, so far as he would permit, to lighten his work recently, and to their son and daughter.

Dr. PRESTON RICHARD WALLIS died on January 26 in Jersey, Channel Islands, where he had lived and worked for more than 30 years. The grandson, son, and brother of medical men, he qualified at University College Hospital in 1896. He practised in London for a time, and became honorary anaesthetist at the East Ham Hospital. In Jersey also he built up a reputation as an efficient and careful anaesthetist. A colleague has sent us the following account of two incidents in which Dr. Wallis figured during the German occupation of the Channel Islands. One bitterly cold night Dr. Wallis was called to see a sick child of a humble family. He found there the remnants of the last inner door smouldering in the fire, while some members of

the family were busy smashing up the only remaining table in the house in order to provide fuel. After attending to the child, Dr. Wallis said he would return presently. He went to his home and by candlelight scraped together the last bits of coal left in the coal cellar and filled a sack, carried it back to the cottage of his patient, and left it at the door. His only words, almost in apology, were, "You see, in my house the heat of those coals would now have chilled me, so you are welcome to them." Another example of his heroism, until now unrecorded, occurred when he was called to see a woman patient who was married to a helpless invalid. The woman, a Jewess, was under orders to report in two hours for transportation to the Belsen extermination camp. She pleaded that he should humanely destroy her. Instead the doctor bundled her into a sack and placed her in the back of his car, under the very nose of the Gestapo, who had her under constant observation. Dr. Wallis knew full well that if caught in this act he would have been shot without a trial, or, at best, would have been transported with the woman. He managed to drive her to the home of some good patients, where she was concealed in the attic and kept and cared for until the liberation. Many people in Jersey and elsewhere will know from their own personal experiences how much they owe to Dr. Wallis, both as physician and as friend.

Dr. CHARLES SEFTON O'NEILL, whose death occurred after a short illness on February 2, spent most of his life in the vicinity of Manchester. He graduated M.B., Ch.B. at the Victoria University in 1903, having won the prize in clinical medicine at the Royal Infirmary. He took the D.P.H. in 1904, and proceeded M.D. with commendation in 1907. After no fewer than three hospital residencies—which fitted him for a busy and successful life in general practice—he went into practice at Hale, Cheshire. There was a break of three years in the first world war when he was able to develop his special interest in radiology in a mobile unit in France, where later he became director of radiology for the Third Army. He was mentioned in dispatches, and later appointed O.B.E. In 1919 he went back into practice—or what was left of it—and he busied himself in what became one of his happiest pursuits, the founding and running of a local medical club. Apart from the B.M.A.—of which O'Neill was a most active member, being chairman of the Mid-Cheshire Division from 1922 to 1924—there was nothing to promote friendship and professional gatherings in the locality, and he felt keenly the need for it. The club which he founded thrived under his unstinting care, and has been a blessing and rallying point for its many members ever since. A few days before his death he announced with quiet satisfaction that he had missed only one meeting of the club in over 30 years. He was originator, treasurer, secretary, and—in the best sense—dictator of it: in these multiple capacities he was constantly in touch with a large local medical circle and also with most of the specialists of the Manchester area. In addition he was an ideal host both to the profession and a large group of friends. Possessors of an "all-the-year-round" flower garden, and keen connoisseurs of a well-stocked vegetable garden, Charles O'Neill and his wife kept the happiest of homes, ever open to welcome friends, consultants, and fellow practitioners alike. A gracious and hospitable atmosphere, alert with interest in the arts and literature, but never overburdened with it, produced its inevitable meed of pleasure and satisfaction in both hosts and guests. In addition to running a big practice, Dr. O'Neill continued from 1919 until two years ago as honorary radiologist to the Altrincham General Hospital, a task which became increasingly onerous and heavy. He many times made himself "royal beggar" for the department, much valuable plant being installed as a result of his unfailing ability in unearthing contributory sources in North Cheshire. Remembering the lean days of 1919, he worked constantly for the protection of practices in the second world war: many returning practitioners to his district had cause to

Continuing **research**

into the pharmacological and clinical effects of dextran solutions
reveals the necessity for a wider range of preparations. Benger Laboratories have
therefore made available

in addition to:—

DEXTRAN-BENGER

5% in saline
(isotonic)

An alternative to plasma in the prophylaxis
and treatment of shock.

a salt-free preparation:—

DEXTRAN-BENGER

5% salt-free
(isotonic—containing 5% dextrose)

Indicated where the administration of electrolytes
and particularly the sodium ion is contra-indicated.

and a 10% solution:—

DEXTRAN-BENGER

10% salt-free
(isotonic—containing 5% dextrose)

For the treatment of toxæmia of pregnancy
and nephrotic oedema.

Pleasurable relaxation

In addition to the established use of Myanesin Elixir in the treatment of neurological conditions associated with muscular rigidity and tremor it has now been successfully employed in the relief of psychological states characterized by anxiety and tension.

Amer. J. Med. Sci., 1950, 220, 23, refers to a group of patients in which anxiety states and obsessional conditions

were present and which following the administration of mephenesin, the active constituent of Myanesin Elixir, obtained complete relaxation. Best results occurred in anxiety states, however chronic, and 47 out of 50 patients treated for this condition improved.

Dosage of from $\frac{1}{2}$ to 1 tablespoonful, one to six times daily, is suggested.

'MYANESIN' ELIXIR

Containing 1 gramme mephenesin in each tablespoonful. Bottles of 8 fl. oz. 6s. 4d.; 40 fl. oz. 26/1d.

Also available in tablets containing 0.5 gramme. Bottles of 100 at 21s. 7d.

Prices in Great Britain to the Medical Profession.

be grateful to him for his work. He was not wholly opposed to the National Health Service—but firmly opposed to a 100% Service and to the unlimited powers vested in the Ministry of Health. The cares, responsibilities, and privileges of practising medicine were to him very vital, and he had the vision to see and dread the possible degeneration of a tradition when these responsibilities are removed from the control of those who have been trained to accept them. An individualist rock-set in a gathering sea of conformity, O'Neill's passing will be noted by a vast circle of friends and medical brethren with profound regret.—P. H. M.

Medico-Legal

TUBERCULOSIS CONTRACTED BY NURSE

APPEAL SUCCEEDS

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

An Industrial Injuries Tribunal has allowed the appeal of a Dundee nurse against a decision of an insurance officer that she was not entitled to industrial injury benefit in respect of tuberculosis which she said was contracted by nursing tuberculous patients.

The nurse, who is now 20 years old, started work as a student nurse in 1947. Before she started she had a medical examination including chest radiography. The result was negative. She worked in several wards as a resident nurse, including a whooping-cough ward. She said that some of the cases she nursed at that time had tuberculous complications, as she knew from entries on the patient's charts, and one at least was later transferred to a tuberculosis ward.

In January, 1948, as a result of a routine x-ray examination which turned out positive she was admitted to a chest hospital. By January, 1949, after a further x-ray examination she was told she was fit to resume work on light duties at first.

She returned to work in a hospital in that month, doing ambulance work and no ward work for the first few months. During that time she dealt with all types of cases that came to the hospital, including cases of "open" tuberculosis. In November, 1949, she was again found to be suffering from tuberculosis, and was again admitted to hospital, where she remained until discharged in April, 1951.

The insurance officer had rejected her claim on the ground that there was no record by the hospital that any of the patients whom she had nursed before January, 1948, were suffering from tuberculous complications. Pulmonary tuberculosis had been diagnosed in January, 1948, before she had come into close and frequent contact with the "open" cases of tuberculosis in the course of her ambulance work, and therefore he did not find that the disease from which she was suffering was due to the nature of her employment. This view was supported in a specialist's report.

In allowing the appeal the chairman of the tribunal said that the nurse was entitled to rely on the presumption in the regulations that the disease was due to the nature of her employment unless the contrary was proved. The tribunal was not satisfied beyond reasonable doubt that the disease was contracted otherwise than as a result of her employment. No satisfactory evidence to that effect had been forthcoming, and the tribunal found in the terms of the regulations that the contrary had not been proved. The nurse will receive 19s. per week extra benefit accordingly.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College, held on February 14, with the President, Sir Cecil Wakeley, in the chair, Loyal Addresses of Condolence to Her Majesty the Queen and to Her Majesty Queen Elizabeth the Queen Mother were adopted.

The Hallett Prize was awarded to J. C. N. Wakeley (King's College Hospital) and a Moynihan Lectureship to Dr. L. Mayer (New York). The award of Proffit Research Studentships to F. Masina and T. R. Munro was reported.

Mr. L. E. C. Norbury and Mr. A. Dickson Wright were nominated as members of the Council of the Imperial Cancer Research Fund.

The Council gratefully received gifts of silver from the Faculty of Medicine of the University of Ceylon.

Diplomas of Membership were granted to D. W. Ebrahim and B. G. Jackson and to the recipients of the Licence of the Royal College of Physicians of London, whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of February 9 (p. 335).

Diplomas were awarded, jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN PUBLIC HEALTH.—J. P. Agrawal, Frances C. Myatt, T. A. Pace, A. C. B. Singleton, W. J. Smither, E. D. H. Williams.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—M. Lwin.

The following hospitals were recognized in respect of surgical posts required of candidates for the Final Fellowship examination: Bury General Hospital (re-designation of posts), registrar; registrar (orthopaedic); senior house-surgeon; senior house-surgeon (orthopaedic); and two house officers, all for six months. Memorial Hospital, Darlington, two surgical registrars, each for one year; surgical house officer (house-surgeon), for six months. Nelson Hospital, Merton, senior house-surgeon, for six months. St. Mary's Hospital, Portsmouth, temporary recognition to be extended for one year. Queen Alexandra Hospital (Army), senior house officer (ophthalmology); senior house officer (otolaryngology) to be recognized for six months for general surgery. Kent and Sussex Hospital, Tunbridge Wells, re-designation of registrar post, already recognized to that of senior house officer (ear, nose, and throat). Tindal Hospital, Aylesbury, additional recognition, house-surgeon, for six months. St. James's Hospital, Leeds, additional recognition, deputy resident surgical officer, one year; first house-surgeon and second house-surgeon, both for six months.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College, held on January 26, with the President, Dame Hilda Lloyd, in the chair, the following were elected to the Fellowship: Y. N. Ajinkya, A. W. Anderson, A. Josephine M. T. Barnes, C. W. F. Burnett, W. D. A. Callam, G. P. Charlewood, S. Davidson, R. de Solderhoff, A. B. Evans, D. B. Fraser, H. F. P. Grafton, G. G. Lennon, W. A. Liston, R. Lyons, H. McLaren, R. F. Matters, B. E. Meek, H. K. Porter, P. G. Preston, D. C. Rackner, G. W. Robson, J. W. Schabert, G. G. L. Stening, S. L. Townsend, J. C. Whyte, R. J. Wotherspoon. N. McA. Gregg was also elected to the Fellowship in recognition of his work on rubella in pregnancy.

Lydia Colaco was admitted to the Membership of the College.

The following were elected to the Membership: E. McL. Barbour, Caroline D. Baugh, R. M. C. G. Beard, D. C. G. Bracken, A. D. H. Browne, K. McL. Crocker, V. Drosso, M. P. Durham, J. Elstubb, B. Eton, M. R. Fell, H. Ferguson, W. T. Fullerton, R. L. Gadd, F. G. Geldenhuys, A. I. I. Klopper, J. B. Lawson, Sarah Lehané, R. D. Macbeth, A. D. McIntosh, D. Magner, D. J. Meagher, A. P. B. Mitchell, N. Moss, T. R. Nelson, E. P. D. O'Neill, C. B. Oxner, J. Price, Monica M. A. Reford, W. H. D. Scotland, H. I. Schmilg, R. S. L. Stafford, Joan E. Storey, E. Sussman, J. S. Tomkinson, F. L. A. Vernon, J. Ward, P. P. Wium.

The Sims-Black Travelling Professor, Mr. G. F. Gibberd, left for South Africa on January 31, on the first stage of his tour.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending February 2 (No. 5) and corresponding week 1951.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.

† Includes primary and influenzal pneumonia.

‡ Includes puerperal pyrexia.

Vital Statistics

Smallpox in Lancashire

There is laboratory confirmation of the diagnosis of variola in a cotton worker resident in Milnrow, Lancs. The woman was unvaccinated. The rash appeared on February 1, fever and constitutional disturbance having started on January 29.

The patient was removed to a smallpox hospital on February 8. Her husband sickened on February 14 and developed a rash on February 17; her daughter sickened on February 16; both were removed to hospital on February 17.

Temperatures of 102° F. (38.9° C.) were recorded during the prodromal stage; thereafter the disease was mild. The rash was discrete and sparse, but the distribution typical of variola minor.

It now seems probable that similar cases exist in the adjacent town of Rochdale, and the matter is being investigated.

Mysterious Rash at Cheltenham

A small outbreak of a puzzling dermatological affection at Cheltenham is reported by the M.O.H., Dr. Donald E. Morley. The first wave of cases began early in January. It was not of long duration, and by the third week in January very few cases were occurring. A second wave appeared in the first few days of February, and the outbreak continues. As the condition is not notifiable and has no serious effects its exact incidence is unknown. But it is estimated that at least 200 cases have occurred, and possibly many more.

The eruption is follicular and of a discrete papular type, with localized irritation; normally there are no general symptoms except occasionally some malaise or vomiting. In a very few bad cases in young children there have been a moderate adenopathy and mild pyrexia. The face, including the retro-auricular region, is most commonly affected. Next in frequency are the back, forearms, abdomen, and legs. After a day or two the rash becomes less prominent, but horny plugs appear in the follicles, and the skin feels like a nutmeg-grater. The eruption disappears in 4-10 days.

The incidence is highest in women and young children, and evidence is still inconclusive about the infectivity or not of the condition.

Investigations into the aetiology and epidemiology of the disease are in progress. Outbreaks may be occurring elsewhere in the country, which, owing to the mildness of the infection, are escaping any significant attention. It is hoped that doctors seeing this condition will inform the M.O.H.s. concerned and that the latter will send the relevant facts to the Ministry of Health (S.M.O., Med. 3), Savile Row, W.1.

Infectious Diseases

In England and Wales during the week ending February 2: an increase was recorded in the number of notifications of measles 549, acute pneumonia 169, and whooping-cough 79, and a decrease of 57 for dysentery.

The notifications of scarlet fever were 27 more than in the preceding week, and only small changes occurred in the general distribution of the cases. A small rise in scarlet fever was recorded in London and each of the south-eastern counties, and the number of notifications for the combined area was 69 more than in the preceding week. The largest rises in the notifications of measles were Norfolk 81, Cheshire 79, Lancashire 67, and Middlesex 75. The notifications of diphtheria were 3 fewer than in the previous week. The chief feature of the returns for diphtheria was the reappearance of diphtheria in the city of Birmingham, where five cases were notified during the week. The largest variations in the trends of whooping-cough were a rise of 48 in Warwickshire and a fall of 63 in Yorkshire.

West Riding. The rise in the incidence of acute pneumonia was most pronounced in London and the south-east counties, where 72 more cases were notified than in the previous week.

The number of notifications of acute poliomyelitis was one fewer than in the preceding week for both the paralytic and non-paralytic cases. The largest return during the week was 4 in London.

The chief centres of dysentery were Norfolk 73 (Norwich C.B. 61); Middlesex 72 (Willesden M.B. 33, Ealing M.B. 10); London 56 (Islington 16, Camberwell 10); Lancashire 54; Yorkshire West Riding 50 (Bradford C.B. 23, Leeds C.B. 10); Warwickshire 22 (Birmingham C.B. 15); Devonshire 21.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1943-51 are shown thus -----, the figures for 1952 thus ————. Except for the curves showing notifications in 1952, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending February 9

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,416, whooping-cough 2,686, diphtheria 34, measles 4,425, acute pneumonia 1,105, acute poliomyelitis 17, dysentery 592, paratyphoid fever 6, and typhoid fever 2.

Medical News

Birthday of the Week.—The British Association of Physical Medicine, founded in 1943, has decided to publish its own quarterly journal, and the first issue of *Annals of Physical Medicine* is out this week, published by Headley Brothers, Ltd., 109, Kingsway, London, W.C.2, at 6s. a copy or a guinea a year. It contains two papers—one an experimental study of the biological effects of micro-waves (centimetric radio waves), the other an account of the ambulant treatment of the complications of varicose veins in over 500 patients. In addition there are book reviews, news, and a useful abstracting section from the *International Review of Physical Medicine and Rehabilitation*. The new journal is very neat in format, and contains an excellent photograph of Lord Horder by way of frontispiece.

Whole-time Specialists.—The first annual dinner of the Association of Whole-time Salaried Specialists was held at the Royal College of Surgeons of England on January 25 and was attended by approximately 60 members. The guests included Sir Max Page, representing the Royal College of Surgeons, Mr. R. E. Jowett, president of the Regional Hospitals' Consultants and Specialists Association, and Mr. J. M. Milloy, of the Medical Superintendents' Society.

Medical Research Council Fellowships.—The Medical Research Council invites applications for the following Travelling Fellowships for the academic year 1952-3:

Rockefeller Travelling Fellowships in Medicine.—These Fellowships are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York. They are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in the United Kingdom. The stipend of Fellowships tenable in the United States will ordinarily be at the rate of \$2,600 per annum for a single Fellow, and of \$3,600 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition.

Eli Lilly Travelling Fellowships in Medicine.—These Fellowships, tenable in the United States, will be provided from a special fund placed at the disposal of the Council by Eli Lilly and Company, U.S.A. Four Fellowships will be available for the

academic year 1952-3, and the awards will in general be made on terms and conditions similar to those attaching to the Rockefeller Travelling Fellowships in Medicine.

Dorothy Temple Cross Research Fellowships in Tuberculosis.—These Fellowships are awarded by the Council from a special endowment of which it is trustee. The object of the Fellowships, as defined in the Trust Deed, is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." The Fellowships will, as a rule, be awarded to candidates who wish to make their studies or inquiries elsewhere than in the United Kingdom. The Fellowships provide for the payment of stipend, together with an allowance for travelling and incidental expenses. The stipend will ordinarily be at the rate of £650 per annum for a single Fellow, and of £900 per annum for a married Fellow, subject to appropriate adjustment in the case of Fellowships tenable at centres outside the sterling area.

Further particulars and forms of application may be obtained from the secretary, Medical Research Council, 38, Old Queen Street, Westminster, S.W.1, with whom applications must be lodged not later than March 15, 1952.

London's New Medical Officer.—The impending retirement of Sir Allen Daley, Medical Officer of Health and School Medical Officer of the London County Council, was announced in the *Journal* of December 8, 1951 (p. 1393). As we go to press we learn that at a meeting of the L.C.C. on February 19 Sir Allen Daley's deputy, Dr. John Alexander Scott, has been appointed in his stead. Dr. Scott, who was born in 1901, became deputy in 1948.

Biological Warfare.—Over 200 scientists wanting to co-ordinate their efforts for peace met in London in January, 1951, and elected a provisional committee to draw up proposals which could be submitted to a national conference of scientists. Such a conference was held in London last month, attended by about 180 eminent scientists; the resolution passed at the International Congress of Microbiology at Copenhagen in 1947 condemning all forms of bacteriological warfare was warmly approved. The conference called upon the Government "to enter into negotiations with other Governments with a view to a general formal repudiation of any use of biological warfare and to work out practical measures to ensure that this repudiation is effective." It further asked that secrecy should not be imposed on workers engaged in research connected with biological warfare, that inspection of their laboratories should be allowed, and also the publication of results.

Emergency Bed Service: Applications and Admissions.—During the seven days ending February 18 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,195, of whom 87.53% were admitted.

COMING EVENTS

Nursing Conference.—The Royal College of Nursing is holding a conference on the mental health services from February 27 to 29 at the College (Cavendish Square, W.1). The fee for the conference is £2 2s., and details may be obtained from the secretary, Royal College of Nursing.

Sub-fertility Conference.—The Family Planning Association is organizing a conference at the Bonnington Hotel, Southampton Row, W.C.1, on February 29 and March 1. Full details from the secretary, Miss I. M. James, 64, Sloane Street, S.W.1.

Service M.O.H.s' Dinner.—The annual dinner of the Services Group of the Society of Medical Officers of Health will be held on March 14 at Simpson's Restaurant, 100, Strand, London, W.C.2, at 7 for 7.30 p.m. The cost per head will be 25s. (exclusive of wines). Members may invite guests, and any serving officer will be welcome. Details may be obtained from Dr. G. M. Frizelle, London School of Hygiene and Tropical Medicine, W.C.1, who would like to be informed as soon as possible who will be present.

Royal Sanitary Institute Congress.—The annual health congress will be held this year at Margate from April 22 to 25. The fee will be £2 2s., but fellows, members, and associates of the Institute will be supplied with tickets free on application to the secretary, from whom full details may be obtained at 90, Buckingham Palace Road, S.W.1.

Study of Fertility.—The annual meeting of the Society for the Study of Fertility will be held in the meeting-house of the Zoological Society of London on June 27 and 28. Further information may be obtained from Dr. G. I. M. Swyer, Obstetric Hospital, University College Hospital, Huntley Street, London, W.C.1.

Association of Surgeons.—The annual meeting of the Association of Surgeons of Great Britain and Ireland will be held in Cardiff from April 17 to 19 inclusive. The full programme will be circulated in March, and all inquiries should be addressed to the honorary secretary, 45, Lincoln's Inn Fields, London, W.C.2.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday

FACULTY OF RADIOLOGISTS.—We very much regret that an error was made in our announcement (February 16, p. 394) of the meeting of the Radiodiagnosis Section on February 22. There will be no meeting on this date.

Sunday

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Adolph Tuck Hall, Woburn House, Upper Woburn Place, London, W.C., February 24, 3 p.m., "*Chemotherapy of Tuberculosis*," by Professor J. M. Robson.

Monday

EDINBURGH UNIVERSITY: FACULTY OF MEDICINE.—At Anatomy Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, February 25, 5 p.m., "*Steroid Hormones and Behaviour: Experimental and Clinical Aspects*," by Professor Marc Klein (Strasbourg).

HUNTERIAN SOCIETY.—At Mansion House, London, E.C., February 25, 8.30 p.m., "*P.P.S.*," Hunterian Oration by Dr. George Day.

INSTITUTE OF PSYCHIATRY. Maudsley Hospital, Denmark Hill, London, S.E.—February 25, 5.30 p.m., lecture-demonstration for postgraduates by Dr. E. Stengel.

LONDON UNIVERSITY.—At University College, Physiology Theatre, Gower Street, W.C., February 25, 5 p.m., "*Antidiuretic Effects of Blood and Urine in Relation to Neurohypophyseal Secretion*," special university lecture in pharmacology by Professor H. B. van Dyke (Columbia University).

MANCHESTER MEDICAL SOCIETY.—February 25. (1) At Lecture Room, Manchester Dental Hospital, meeting of Section of Odontology, 5 p.m., "*The Price of Medical Progress*," by Dr. A. Morgan Jones; (2) At Physiology Theatre, Medical School, Manchester University, meeting of Section of General Practice, 9 p.m., "*Tuberculosis and the General Practitioner*," by Dr. Marc Daniels.

Tuesday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 26, 5.30 p.m., "*Research on Ageing*," by Professor E. C. Dadds, F.R.S.

EDINBURGH UNIVERSITY.—At Anatomy Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, February 26, 5 p.m., "*The Chemistry of the Adrenal Cortical Hormones*," Cameron Prize Lecture by Professor Tadeus Reichstein (Basle).

● **INSTITUTE OF DERMATOLOGY.** Lisle Street, Leicester Square, London, W.C.—February 26, 5.30 p.m., "*Leprosy*," by Dr. R. G. Cochrane.

LONDON UNIVERSITY.—At Westminster Medical School, Horseferry Road, Westminster, London, S.W., February 26, 5.30 p.m., "*The Pathology and Treatment of Portal Hypertension*," special university lecture by Professor Milnes Walker.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. Lincoln's Inn Fields, London, W.C.—February 26, 5 p.m., "*Partial Nephrectomy in the Treatment of Renal Calculi*," Hunterian Lecture by Professor H. H. Stewart.

WEST END HOSPITAL FOR NERVOUS DISEASES. 40, Marylebone Lane, London, W.—February 26, 5.30 p.m., neurological demonstration by Dr. C. Worster-Drought.

Wednesday

CAMBRIDGE UNIVERSITY.—At Department of Physical Chemistry, Free School Lane, Cambridge, February 27, 12 noon, "Some Aspects of the Physical Chemistry of Amino-acids, Peptides, and Proteins," by Professor John T. Edsall (Harvard University).

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 27, 5.30 p.m., "Histopathology of Leprosy," by Dr. R. G. Cochrane.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., February 27, 4.30 for 5 p.m., "Differential Diagnosis of Frequency of Micturition," by Mr. Harland Rees.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—February 27, 8.30 p.m., "The Surgery of the Heart and Great Vessels," Second Lettsomian Lecture by Mr. R. C. Brock.

●ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C.—February 27, 2.30 p.m., "The Work of the National Research Development Corporation," by the Right Hon. the Earl of Halsbury, F.R.I.C., F.Inst.P.

Thursday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 28, 5.30 p.m., "Lability of Blood Pressure," by Professor M. L. Rosenheim.

CENTRAL MIDDLESEX HOSPITAL, Acton Lane, Park Royal, London, N.W.—February 28, 10.15 a.m., clinical meeting open to all consultant physicians in area of North-west Metropolitan Regional Hospital Board. Details from Regional Adviser in Postgraduate Medical Education, 2, Gordon Square, London, W.C.1.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY, The Union, University Avenue, Glasgow.—February 28, 7.30 p.m., address by Sir Geoffrey Jefferson.

●INSTITUTE OF CHILD HEALTH, Hospital for Sick Children, Great Ormond Street, London, W.C.—February 28, 5 p.m., "Plastic Surgery," by Mr. D. N. Matthews.

INSTITUTE OF PHYSICS: MIDLAND BRANCH.—At The University, Edgbaston, Birmingham, February 28, 5 p.m., "Some Applications of Physics to Medicine," by Professor F. W. Spiers.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—February 28, 4.30 p.m., lecture-demonstration in psychiatry by Dr. D. Curran.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, Lisle Street, Leicester Square, London, W.C.—February 28, 4.15 p.m., demonstration and discussion of clinical cases; 5 p.m., "Leprosy," talk by Dr. R. G. Cochrane.

UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—February 28, 4.45 p.m., "Mitochondria and Biological Oxidations and Phosphorylations," by Dr. A. L. Lehninger (Chicago).

Friday

CHURCHES' COUNCIL OF HEALING.—At Alliance Hall, Palmer Street, Westminster, London, S.W., February 29, 7 p.m., "The Vision of the Future," by Dr. E. E. Claxton (Assistant Secretary, B.M.A.).

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—February 29, 5.30 p.m., "Leprosy," clinical demonstration by Dr. R. G. Cochrane.

●INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 29, 5.30 p.m., "Surgical Aspects of Patent Ductus Arteriosus and Coarctation," by Sir Clement Price Thomas.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W.—February 29, 7.30 p.m., general meeting. "What is the Value of the G.F.T.?" by Dr. F. R. Curtis. A discussion will follow.

OXFORD UNIVERSITY.—At Magdalen College, Oxford, February 29, 5 p.m., "The Neurophysiological Basis of Mind," Waynflete Lecture by Professor J. C. Eccles, F.R.S.

ROYAL INSTITUTION, 21, Albemarle Street, London, W.—February 29, 9 p.m., "The Brain as a Machine," by Sir Henry Cohen.

UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—February 29, 5.30 p.m., "Cell Physiology and Pharmacology—Some Cytochemical and Cytological Aspects of Drug Action," by Professor J. F. Danielli, D.Sc.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Du Heaume.—On February 7, 1952, at the Windmill Nursing Home, Enfield, to May (formerly Giffin), wife of Brian Du Heaume, M.B., B.S., 21, Byculla Road, Enfield, Middlesex, a son—Alan.

Levy.—On February 13, 1952, to Enid (formerly Glyn), wife of Dr. Basil Levy, of Liverpool, a son—Peter.

MARRIAGES

Campbell—Stewart.—On February 9, 1952, in Manchester, Ross Campbell, A.M.I.C.E. of Warrington, to Diana Stewart, M.B., Ch.B., of Lancaster.

Heumann—Howells.—On February 9, 1952, at St. James's Church, Muswell Hill, London, N., Paul Clifford Heumann, B.A., to Désirée Howells, M.R.C.S., L.R.C.P.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Choose Your Analyst

Q.—A patient has been recommended psycho-analysis. Relatives are anxious that he should have an Adlerian rather than a Freudian analysis. What, briefly, are the main differences? What other forms of analytical treatment are available?

A.—The main practical difference between an Adlerian and a Freudian analysis is in the time involved, a Freudian analysis commonly taking two years or more, an Adlerian analysis seldom requiring more than a year. There are very wide differences between Adlerian and Freudian theories, and in the sort of interpretations which will be made by analysts of the two kinds to the patient. Adlerian theory is simpler and easier to understand, and relates most psychiatric symptoms to repressed feelings of inferiority, often associated with some particular part of the body. It is, as a rule, much more important to choose the right psychotherapist than to bother about the school he belongs to; the general practitioner should try to find a therapist who has plenty of common sense and will try to get practical results, rather than one who is hidebound in theory. Apart from Adlerian and Freudian analysis, there is also Jungian analysis; and there are psychotherapists who are eclectic, who make use of elements from all three types of theory, or who rely on explanation, persuasion, suggestion, and other methods which are the specific property of no dogmatic theory.

Judo Neck-strangle

Q.—What is the mechanism of the Judo neck-strangle? This is sometimes used as a "hypnotic trick," and death can occur through vagal inhibition. I understand that Judo experts have some method for reviving those rendered unconscious by this strangle, such as striking a thoracic vertebra sharply with the knee.

A.—The neck-strangle used in Judo is considered to act by compressing the common carotid arteries, so temporarily depriving the brain of its blood supply. Whether it ever acts by stimulation of normal or over-sensitive carotid bodies is not known: as the function of the carotid bodies has only recently become known to the medical profession and is not yet clearly and completely understood, further research would be needed to decide whether the unconsciousness produced by the neck-strangle is partly or entirely or occasionally due to stimulation of this kind. The time taken to produce unconsciousness would suggest that it may occasionally be so. No fatal case seems to have been reported over many years in Japan or elsewhere, and the process of being strangled in this way is not in any way painful. It often occurs when one is resisting a strangle, apparently successfully, and one may find oneself powerless to tap (recognized signal of defeat) by the time one realizes that the strangle has been effective.

In practice the Judo hold is simple enough but easier to demonstrate than to explain on paper; generally the supinated forearms are crossed, the fingers (not thumbs) inserted deeply behind the collar of the jacket as far back as possible, the thumbs on the outside of the collar or lapel helping to keep the collar secure; a scissors action of the forearms brings the radial edges against the neck just below the mandible, and increasing pressure compresses the arteries: there are, of course, variants of the technique.

In ordinary practice one taps when the pressure is correctly applied in the first instance; strangulation is rarely produced and, if so, is usually involuntary, as described above.

"Kuat-su," or the resuscitation of unconscious people, has many techniques, and these are taught only to instructors who have achieved the level of Black Belt: "striking a thoracic vertebra sharply with the knee" could be a rather crude description of one of the techniques that may be used. These techniques have not been put on paper because inexperienced and irresponsible people might indeed resort to striking a thoracic vertebra with the knee to the grave risk of the sporting population. Generally, they are sharp—but carefully graduated—taps on the spine, epigastrium, or one or two other points whose effects have been investigated empirically over a long period. They seem to produce reflex stimulation which may stimulate an individual who is unconscious in the way that—and under the conditions where—any counter-shock may do so. Whether they have any other virtues or efficacy, or can revive those who do not react to Western methods of resuscitation by injection, etc., I cannot say. So far as I know the matter has never been investigated scientifically.

Notification of Pemphigus Neonatorum

Q.—Is pemphigus neonatorum a notifiable disease? I understand a midwife in domiciliary practice has to notify it to the supervising authority. What is the duty of the doctor in these cases? Also, what is the duty in this respect of an obstetrician in charge of a maternity hospital (a) in England, and (b) in Scotland?

A.—Pemphigus neonatorum is not a statutorily notifiable disease like diphtheria or scarlet fever. Under the rules of the Central Midwives Board, however, and possibly also on instructions issued by the local supervisory authority, it is incumbent on the midwife who recognizes any abnormality, including pemphigus, in an infant under her care (a) to summon medical aid, after which the doctor called in attendance becomes responsible for the treatment of the case, and (b) to notify the local supervisory authority, which then takes the responsibility for investigating the circumstances of the case and dealing with the midwife. When a case or cases occur in a maternity unit the medical officer in charge is ordinarily responsible for control measures, but he will usually find it expedient to notify the medical officer of health of the local sanitary authority and get his co-operation.

As pemphigus neonatorum is not notifiable in either England or Scotland the same procedure should be adopted in both countries.

Proprietarys for Asthma

Q.—Is it justifiable to prescribe on E.C.10 proprietary remedies for asthma which are substantially the same as the National Formulary neb. adrenal. et atrop. co.? Some of my asthmatic patients find the proprietary products more helpful.

A.—There are minor differences in composition between proprietary preparations and the National Formulary neb. adrenal. et atrop. co. It is a common experience for patients to state that the National Formulary preparation is less effective than one or other of the proprietary preparations. Although it is difficult to exclude with certainty the suggestion that psychological factors play a part, in the writer's experience this is improbable, because in many cases patients have thought they were receiving an identical product. It is easy to recognize the difference between these preparations when given "blind" to patients. On the whole, therefore, I consider that it is justifiable to prescribe the proprietary remedies on E.C.10 when a patient states that they are definitely more effective than the National Formulary preparations in his case.

Brimstone and Cancer

Q.—What are the medical causes of a taste and smell of sulphur? This was a leading symptom in a woman with cancer of the breast. The symptom disappeared about three weeks after radical mastectomy, but has now recurred; so far there is no evidence of recurrence of the growth. Is there any possible association between the cancer and the taste of sulphur?

A.—There appear to be no references in the literature to an association of cancer with a taste of sulphur. L. S. P. Davidson (*Lancet*, 1949, 2, 197) refers to the odour of mercaptan in the breath of patients with severe liver disease. H. G. Crabtree (*Cancer Res.*, 1946, 6, 553) refers to evidence of a direct association between sulphur compounds in the cells and carcinogenic substances during the early stages of carcinogenesis; this association may be related to the normal process of detoxication, and may play a part in carcinogenesis.

Geographical Tongue

Q.—What are the causes and treatment of geographical tongue?

A.—Geographical tongue is a description applied to the appearance of bald patches on the tongue due to exfoliation of the surface horny layer. The patches may coalesce in a discoid pattern resembling alopecia areata of the scalp, and like this condition are functional in origin. Geographical tongue may occur alone or in association with functional dermatoses, especially of the exudative type such as urticaria, eczema, and seborrhoeic dermatoses. The condition is of no significance, it is usually symptomless, and like the accompanying dermatological ills is not responsive to any line of treatment; it may wax and wane or clear up completely.

NOTES AND COMMENTS

Seasickness.—Dr. GILBERT DALLEY (London) writes: I must take issue with your correspondent writing on seasickness ("Any Questions?" January 5, p. 57) who maintained that antihistamine-like drugs were less effective than hyoscine. I am not a sufferer myself, but from experience in small boats I can assure your readers that, if they wish to have a comfortable sea trip with all their faculties unimpaired, drugs such as "dramamine" or better still "avomine" are far preferable to hyoscine, and those who are sufferers from *mal de mer* will be able to enjoy going to sea.

OUR EXPERT writes: Dramamine is the 8-chlorotheophyllinate and "benadryl" the hydrochloride of diphenhydramine; the pharmacological action of dramamine and benadryl is the same (M. Nickerson, *Science*, 1950, 111, 312). Equally the pharmacological action of avomine (promethazine-8-chlorotheophyllinate) and "phenegan" (promethazine hydrochloride) is the same. Experiments performed in small boats and designed to exclude personal prejudice (E. M. Glaser and G. R. Herve, *Lancet*, 1951, 2, 749) have shown that hyoscine is a better seasickness remedy and no more toxic than either benadryl or phenegan. The patients in these experiments took each drug in turn but did not know what drugs were used, and they preferred hyoscine.

CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

REGISTRARS AND REDUNDANCY

An all-day meeting of the Committee was held at B.M.A. House on February 7, Dr. T. ROWLAND HILL presiding. The members stood in silence as a tribute to the late King.

The position of registrars and senior registrars whose contracts had been terminated as a result of the reduction in registrar establishments was the subject of a long discussion. The CHAIRMAN said that there was one particular aspect of the registrar problem which the Joint Committee would raise again with the Ministry of Health—namely, the problem of the transferred officer who was wrongly graded at the outset of the National Health Service as a registrar or senior registrar, and was now, although a permanent officer, in danger of losing his appointment.

The Joint Committee had had difficulty in reaching agreement with the Ministry on this point, but it would be pressed again that such officers should have their gradings rectified so that they became, for example, S.H.M.O.s, where that was really the appropriate grading. He was told that the people particularly affected were transferred officers—that is, men who had a permanent job in the local authority hospitals prior to 1948 and could not be graded as consultants and so were graded inappropriately as senior registrars, the precise function of the S.H.M.O. grade, and even of the S.H.M.O., being in doubt then, so much so that grading committees often avoided the grade. There were a considerable number of these, and there was no machinery whereby the mistake of three years ago could be corrected and the men be graded S.H.M.O.s.

Another problem concerned the hardship to men who had been senior registrars for a number of years and were likely to find themselves very shortly in difficulties concerning employment. The Joint Committee urged the taking of some short-term compassionate action.

A spokesman of the Registrars Group Committee said that within a measurable time the number of senior registrars was to be cut to 960; at the moment it was considerably more than this, and many were coming to the end of their extended term of office. In some cases they had had a raw deal. They had been taken in on the post-war tide of expansion and their prospects were too rosy painted. The simple fact was that there were more highly

trained people than could be absorbed immediately. One line of Ministerial policy, if it could be followed, might help the registrar situation. Within the near future about 270 consultants over the retiring age would have their position reviewed, and if something near this number of vacancies were created over and above the normal expectation a corresponding number of registrars could be absorbed. It was felt that at this particular moment for registrars to have their contracts terminated abruptly when during the next 18 months or so a number of them might be absorbed was a mistake which would have unfortunate reactions, not only on the registrars themselves but on the service.

Alternative Employment for Registrars

Mr. C. E. KINDERSLEY said that this was really a two-fold problem—the problem of existing registrars and that of the registrars of the future. So far as the latter were concerned, the Joint Committee had done a great deal to ensure that they would not be “led up the garden path,” and that their appointments would be more or less in accordance with vacancies. But at present there were a large number of senior registrars concerning whom the Government had a real responsibility. Everything possible should be done to make the Government realize its obligation towards these young men. Many were likely to come under notice and would find it extremely difficult to get employment at all. The original grading was never very satisfactory so far as registrars and S.H.M.O.s were concerned; some who were created senior registrars were graded wrongly. Some were graded in the expectation that they would receive consultant posts, but they had not done so, not through any demerit of their own, but because it was thought that someone who had worked in a teaching hospital was necessarily better than one who had done most of his work in a non-teaching hospital. Some of the senior registrars who were likely to be dismissed within the next few months were approaching the age of 40. There were the transferred officers, who were finding themselves in an awkward position. There were those who had returned from the Services and accepted registrar posts on the understanding that the country was very short of consultants. The Government had suggested the Colonial Medical Service as alternative employment, but at the age of 35 to 40 this did not offer very much, especially with a retiring age at 55, when the men would be back in this

country with less opportunity than ever of getting a job. For the younger people there were opportunities in general practice, though from what he had heard the ex-registrar was not greatly welcomed in that field. An appeal might be made to the General Medical Services Committee to see that the former registrar had priority in general practice over the newly qualified man just leaving the medical school. The CHAIRMAN said that the problem of the entry of ex-registrars into general practice had already been discussed with general practitioners' representatives and raised with the Ministry of Health.

It was agreed that the Joint Committee should be asked to use all its efforts to remind the Ministry of its grave responsibility towards these men, and also that the G.M.S. Committee be reminded of the general practice aspect. A resolution from the Registrars Group Council calling for more flexibility in the terms of office of registrars and senior registrars was also referred to the Joint Committee.

The CHAIRMAN said that a suitable way to deal with the problem would be to make the term of the senior registrar more flexible. A general resolution such as that just passed that the attention of the Government be drawn imperatively to the position of these men was the best course at the moment.

The registrars' representative thanked the Committee for its interest in their affairs. Asked whether there would be "toughness" on this matter, the CHAIRMAN said that the view of the Committee would be put forward that a strong, outspoken, and determined attitude must be taken up to deal with this short-term position. The solution was clear enough; the difficulty was to bring enough persuasion or pressure upon the officers of the Ministry.

It was agreed that a further request should go forward to the G.M.S. Committee for help in placing registrars in general practice and for its advice and suggestions in this matter.

Appointment of Consultants and Registrars

A request was received from the Amending Acts Committee of the Association for the views of the Committee concerning the procedure for the appointment of consultants and registrars.

The CHAIRMAN said that a long time ago the Joint Committee asked for certain alterations to be made in the way in which consultants were appointed. A report on the matter went through the B.M.A. machinery and was adopted by the Annual Representative Meeting. The Joint Committee was now in negotiation with the Government. The negotiations were necessarily delicate and difficult, and he hoped that the Amending Acts Committee would leave the matter at that. The moment there was anything to report it would come to the B.M.A. Council. The Council had passed a resolution strongly supporting the common front maintained between the Colleges and themselves. The common front meant that matters at the planning stage must be brought before the constituent bodies, for joint planning together at the earliest possible moment.

Dr. E. C. WARNER said that the Amending Acts Committee was most anxious to co-operate in the presentation of a common front, and he agreed that the common front meant joint planning and joint negotiation from the earliest moment.

Pay-beds

On the subject of pay-bed regulations the CHAIRMAN reported that the detailed schedule of fees for surgical operations in private wards was being discussed with the Ministry and Government policy in regard to amenity beds and maintenance changes for private beds was being considered by the Joint Committee with a view to its full discussion later with the Minister. It was agreed to await a further report and to bear in mind that the profession might have to accept some sort of appeals machinery for doctor or patient in the event of dispute with regard to fees.

Inquiry into Consultant Services

It was reported that discussions had taken place with the Ministry on the action of the South-west Metropolitan Regional Board in reviewing the contracts of individual consultants, and that the Ministry had undertaken to inquire into the position. In the meantime the following broad principles had been accepted: that once a permanent contract had been entered into it should not be disturbed unless it could be clearly shown that altered circumstances justified a variation, in which event due notice should be given and any modification made after a full examination and in agreement with the consultant concerned; and, in the second place, that where a consultant had given up other commitments in order to assume responsibilities offered by a hospital board the board should be under some obligation to maintain the contract for a reasonable time, provided the consultant played his part.

Mr. NICHOLSON-LAILEY said that under a contract the sessions should be based on average speed of work with an average consultant and the average type of patient. There was a tendency to alter such conditions.

It was agreed that the question so far as it had been taken should be referred to the Joint Committee especially in view of the fact that previously the Ministry had agreed that it had a "moral obligation" to do "all in its power" to safeguard the part-time consultants' security of sessions.

Patients' Consent to Operation

Dr. ROBERT FORBES attended by invitation to explain the legal position concerning model forms of consent to operation which had been approved by the Medical Defence Union, and had previously been the subject of some questions in the Committee. Dr. Forbes said that these forms had been prepared after long discussions with counsel and were in operation in most hospitals throughout the country. In practice it was believed that they were advantageous both to the consultant and to any legal bodies which might be called upon to assist him if his conduct was challenged.

Strictly speaking, it was illegal to do anything to anybody without consent, and a practitioner could be charged in the criminal courts with assault, or in other courts he might be found guilty of trespass for which damages could be awarded. Consent could be either implied or written, and many operations were undoubtedly carried out under conditions of implied consent. Lawyers said that a written form of consent was of no use unless it described what was proposed to be done, and some surgeons attached themselves to the view that it was undesirable to disclose this, and that in many cases it was not really known what extent of operation would be necessary. But he thought it was not beyond the wit of surgeons to find a suitable term to cover such cases. "An abdominal exploratory operation" might serve as long as the ensuing part had been faithfully observed—that is, "the effect and nature of which has been explained to me." He did not think it very important what surgical term was used. But it was because it had happened that people had given consent and had subsequently claimed that the authority they gave had been exceeded that it was desired in the form to give as close a description as possible of what it was proposed to do.

The CHAIRMAN said that he hoped these supplementary explanations might be of use and further the acceptance of the model form.

The question of complaints machinery was brought up by Dr. COCHRANE SHANKS. Recommendations had already been made concerning the procedure to be followed by hospital authorities when an incident occurred which might give rise to subsequent complaint or legal action against the hospital or members of the medical staff or both, or again when a complaint was made regarding the personal conduct of a member of the medical staff. The two defence societies, however, which had examined the report and recommendations took different views at certain points, and

therefore he proposed, and it was agreed, that the problem be referred to a joint co-ordinating committee of the defence societies.

A number of resolutions from regional committees and other reports and correspondence were considered.

HOSPITAL MEDICAL STAFFS DEFENCE TRUST

A meeting of the Hospital Medical Staffs Defence Trust was held on February 7 under the chairmanship of Dr. ROWLAND HILL. It was reported that a further letter of appeal for contributions to the Trust Fund was being sent to all members of hospital medical staffs above the grade of house-officer. In the course of discussion it was suggested that the best way to raise funds was by deduction at source in the same way as the National Insurance Defence Trust money had been raised, and it was agreed that a clear and informative statement on the subject should be published in the *Supplement*.

A member of the Trust made the suggestion that consultants should submit to an annual levy—say half a guinea—to meet the expenses of the committee. Another suggestion was that a sum of 1s. for every £100 remuneration should be deducted at source. The Executive Committee of the Trust was asked to look into the matter. The CHAIRMAN thought that an offer might well be made to cover the actual cost of the meetings of the Central Committee during the year. It was mentioned that each meeting of the Committee involved railway expenses to the amount of about £200. It was agreed immediately that, pending further examination by the executive committee, a loan be made from the consultants' defence fund to assist in meeting some of their costs during the next year.

CARIBBEAN COUNCIL OF THE B.M.A. FIRST MEETING IN JAMAICA

Following the visit a year ago of Dr. Guy Dain to the West Indian Branches, a Caribbean Council of the British Medical Association has been formed. Its first meeting was held in Jamaica from December 4 to 7, 1951, under the chairmanship of Dr. W. E. McCULLOCH, past president of the Jamaica Branch, and was attended by delegates from all the Branches in the Caribbean area. Three official observers were also present—namely, Dr. J. W. Harkness, medical adviser to the Comptroller for Colonial Development and Welfare, Professor E. Cruickshank, Dean of the Medical Faculty, University College of the West Indies, and Dr. P. F. DeCaires, Caribbean representative of the World Health Organization. The last-named said that it was intended to extend the small office of the W.H.O. in Jamaica so that it would become the head office for the Caribbean. He hoped for the establishment of liaison between the W.H.O. and the B.M.A.

The Conference was formally opened by the Hon. DONALD SANGSTER, Minister for Social Services, Jamaica, who described the Council as another link in the closer association which was rapidly coming about between the British islands of the West Indies. A welcome was also given by Dr. L. W. FITZMAURICE on behalf of the Jamaican Government medical services, which he claimed to be one of the best of the Colonial units. A reply on behalf of the visiting delegates was made by Dr. P. V. SOLOMON, of Trinidad.

At the business session it was decided that the Council should be called "The Caribbean Council of the Branches of the British Medical Association," and consist of seven members, being one each from Jamaica, Trinidad, Barbados, British Honduras, British Guiana, Windward Islands, and Leeward Islands; that its objects should be to represent the regional interests of the British Medical Association, to place at the disposal of the authorities the advice and co-

operation of the medical profession, and to be the sole advisory and negotiating body for the entire profession in the British Caribbean on regional matters and on subjects submitted by any of the Branches. The meetings are to take place at intervals of not longer than one year (the next is to be at Barbados in December, 1952). Dr. W. J. S. Wilson, of the Jamaican Government Medical Service, was appointed the secretary.

Unification of the Service

Each of the delegates gave the views of his Branch on the question of unification of Caribbean medical services. The only opponent of unification was the Barbados delegate (Dr. A. P. MUIR), who feared that such a course would react to the detriment of the smaller Colonies. Some of the other delegates, while agreeing to unification in principle, had no particular suggestions to offer, and the CHAIRMAN commented on the unsatisfactory nature of the reports. It was agreed, however, that the Branches should get into touch with their respective Governments and ascertain their reactions to the proposal.

The question of standardization and improvement in salary scales and conditions in the Government medical services was also discussed. The accounts given by delegates showed great variations in Government provision and in the emoluments of the profession.

In view of these variations, the secretary was instructed to prepare a report on the subject for the next conference. The CHAIRMAN said that the only solution was a central pool for salaries and a system whereby patients who could do so would be required to pay for treatment in Government institutions. It was the view of the Conference that if there was a more rigid system for collection of hospital payments it would be possible to improve the salaries of medical officers.

Hospital Facilities for Private Practitioners

Another matter which engaged the attention of the Conference was the provision of hospital facilities for private practitioners. The CHAIRMAN urged the establishment of hospital boards which would have, among other duties, the appointment of suitable practitioners to part-time posts in hospitals. The Trinidad delegate, Dr. P. V. SOLOMON, said that it was the general feeling in his colony that the only way in which general practitioners could associate themselves with the work of the hospital was through out-patient clinics. The British Honduras delegate, Dr. PEREZ-SCHOLFIELD, said that there the official attitude was not to allow private practitioners to attend patients in hospital. Dr. HILTON Ho said that in British Guiana private practitioners had recently approached the Government with the offer to run some out-patient clinics and also to take under their care any patients from the clinics whom it was desired to admit to a bed.

Incidents between magistrates and members of the medical profession in murder cases and cases of sudden death were reported, when medical officers not versed in pathology had failed to give clear evidence of cause of death. The Conference therefore resolved to ask the Branches to urge their respective Governments to provide at least one practitioner trained in medico-legal work.

The question of over-population in the Caribbean found the delegates in disagreement on the rightness or expediency of birth control, but a resolution was carried that the problem of population pressing on limited economic resources should be examined by the Branches and that the Governments should be urged to use every method open to them to increase production and improve social conditions.

It was also decided to take steps to bring to the attention of the authorities the urgent necessity for establishing a centre, preferably in Jamaica, but to serve the other islands, for radiotherapy, and to ask for the services of visiting specialists in oto-rhino-laryngology and in orthopaedics in the Windward and Leeward Islands.

B.M.A. Branches and Governments

From Trinidad it was reported that the Government recognized the British Medical Association as a body to be consulted about impending legislation, but the Association's recommendations were often not accepted. From Barbados it was reported that the D.M.S. did not accept the B.M.A. as a recognized negotiating body, and preferred to negotiate through the Civil Services Association, but the Government was now willing to consult with the Branch on certain matters.

The Conference agreed to continue to press for the recognition of the Association as the sole bargaining body for the medical profession in the British Caribbean.

One event of the meeting was a conference with representatives of the Press, who were informed of a Press Relations Committee inaugurated by the Jamaica Branch. The spokesman of the Press promised that there would be no breach of confidence on the part of West Indian journalists.

In closing the Conference after a four-days sitting Dr. McCulloch from the chair thanked the parent Association in London for the part it had played in the development of medical organization in the Caribbean.

A number of social functions accompanied the Conference, including a dinner at which the Governor, the Principal of the University College of the West Indies, and other personages were guests.

ENTRY INTO GENERAL PRACTICE**ELUSIVE PARTNERSHIPS**

Vacancies for prospective partners have declined steadily since the peak period in the second quarter of 1950, according to the 1951 Annual Report of the B.M.A.'s Medical Practices Advisory Bureau. The following Table from it compares the number of assistantships with view and without view to partnership arranged by the Bureau.

	1949	1950	1951
• Assistants with view	235	276	211
Assistants without view	217	422	435

During the second quarter of 1950, 80 prospective partners were introduced, whereas in the corresponding quarter of 1951 the number was 44; in the third quarter of 1951 it was down to 40. In the last quarter of 1951 the figure reached 62, but it is too early yet to say whether this rise will continue.

Experience gained by the Medical Director, Dr. L. Potter, B.M.A. Assistant Secretary, shows that established general practitioners are increasingly reluctant to take partners. In his opinion this is due mainly to two factors—apart from the rising cost of living, which affects all alike. First, the long uncertainty about general practitioners' remuneration makes a doctor loath to commit himself until he can plan ahead more surely. Secondly, there is no capital sum to offset the initial loss of income when a share is transferred.

Heart-breaking Experience

Starting a new practice in London is nothing short of heart-breaking in most cases, according to London Executive Council's evidence to the Central Health Services Council's Committee on General Practice.

According to this evidence, partnerships are sometimes entered into with conditions which make the position of the new partner very little different from that of a hired servant. A vacancy with a reasonable list and residence and surgery often draws some 70-80 applications. In too many cases, says the report, a doctor other than the one approved by the Medical Practices Committee gets round the regulations by obtaining the premises of the out-going doctor.

INFLATION OF LISTS**AGREEMENT WITH G.M.S. COMMITTEE**

The Ministry agrees that doctors should not make personal calls to trace patients. This is one of the points included in a circular (E.C.L.4/52) issued to executive councils by the Ministry of Health after agreement with the General Medical Services Committee.

The circular gives instructions on how to trace patients by means of the local electoral register, the local housing authority, by letter, and if necessary by a personal visit from a member of the executive council's staff. If a person is not traced after six months from the date of the original notification on form E/D, he is to be removed from the doctor's list. If he goes to the doctor within six months of the date when his name was removed, back credits will be made to the doctor, provided there is reason to believe he was at risk to treat the patient during this time.

PUBLIC HEALTH SERVICE**MORE AUTHORITIES IMPLEMENT AWARDS**

More local authorities continue to fall into line and implement the awards made by the Industrial Court. By February 14, 78% of all authorities and 87% of local health authorities in England, Scotland, and Wales were implementing both awards. These figures have increased by about 5% to their present size in three weeks. The following figures show how local health authorities are acting in this matter.

	1st Award	2nd Award
• Counties	93%	91%
County boroughs	75%	80%
Counties of cities	75%	100%

The position continues to improve daily.

COLONIAL MEDICAL SERVICE**SALARIES IN THE FAR EAST**

The Association's negotiations with the Colonial Office continue to bear fruit. The following improved salaries in the Colonial Medical Service can now be announced:

Hong Kong

Director of Medical Services	£2,585
Deputy Director of Medical and Health Services	£2,210
Senior Specialists	£2,210
Deputy Director of Medical Services	£2,135
Deputy Director of Health Services	£2,135
Senior Medical and Health Officers	£1,998
Specialists	£1,998
Medical and Health Officers	£1,148 to £1,911
Special Grade Medical Officers: Medical Officers holding certain higher qualifications enter the Medical Officer scale two increments above the minimum.	

NOTE.—The above figures include expatriation pay.

Malaya and Singapore

	Without Expat. Pay	With Expat. Pay
Administrative Medical Officers—		
Grade A	£1,680	£1,988
Specialists—Grade A	£1,680	£1,988
Administrative Medical Officers—		
Grade B	£1,470	£1,750
Specialists—Grade B	£1,470	£1,750
Special Grade Medical Officers: Medical Officers possessing certain higher qualifications enter the Medical Officer scale four increments above the minimum.		

Western Pacific

Senior Medical Officer—British Solomon Islands	£F1,550 to £F1,650
Senior Medical Officer—Gilbert and Ellice Islands	£F1,600
Medical Officers	£F840 to £F1,550

NOTE.—£F111=£100 sterling.

MALTA BRANCH**INVITATION TO SERVICE MEMBERS**

The Malta Branch of the B.M.A. is the only active medical society on the Island, and during 1951 its membership rose. Six scientific and clinical meetings were held, at which the material presented for discussion was interesting and varied. The Branch Council met on five occasions. The Branch now has its own premises in the form of a room at the British Institute, kindly made available by the British Council. The Branch Library is housed here.

Service members stationed in Malta are invited to participate in the activities of the Branch.

Scottish News**N.H.S. COSTS RISE****Hospital Services**

Compared with 1949-50, the year 1950-1 showed an increase of about £2.7m. in the gross expenditure on hospital running costs in Scotland. Of this, about £570,000 for maintenance of patients is attributable to a 2% increase in the average number of patients and to a rise in commodity prices. The average bed-day cost rose from 18s. 4d. to 19s. 8d.; the average out-patient rate from 4s. 3d. to 4s. 8d. per attendance. A rise of £415,000 in the specialist services was mainly for arrears in consultants' distinction awards. Administrative costs rose by about £80,000 because of increases in salaries and wages due to the filling of authorized staff vacancies.

General Medical Services

Executive council costs fell slightly from £17.266m. to £17.253m. owing to a reduction in the cost of dental services. Against this there were increases of about £90,000 for medical services and £275,000 for pharmaceutical services. The medical services' £90,000 is made up mainly of an increase of £66,000 for training grants for assistants and of £22,000 for superannuation contributions met by executive councils.

Prescribing Check

Payments to chemists rose from £3.8m. to £4.1m. The number of prescriptions dispensed rose from 18,000,000 to 20,200,000, and the average cost from 46.4d. to 50.0d. In March, 1951, the Department of Health notified executive councils that it proposed to take more effective steps to detect and deal with extravagant prescribing. By December about 120,000 prescriptions had been investigated and a number of them selected for reference through executive councils to the local medical committees.—Report of the Comptroller and Auditor General (N.H.S. (Scotland) Act, 1947. Accounts, 1950-1. H.M.S.O. 1s.).

STARTING SALARY OF CONSULTANT**SUCCESSFUL APPEAL**

The B.M.A. has recently won another appeal for a consultant through the regional Whitley appeals machinery.

A Scottish chest physician who had held hospital appointments with full clinical charge before the war took up a public health appointment in 1938 as deputy medical officer of health. But he continued certain clinical consultant duties in infectious diseases, including tuberculosis. In 1940 he took over part of the work of the tuberculosis officer for his county, and in the latter part of 1944 was appointed physician superintendent of a tuberculosis sanatorium in addition to his duties as tuberculosis officer.

In fixing his starting salary as from July 5, 1948, the hospital board disregarded all the clinical consultant service prior to 1944, when the officer took up his present sanatorium appointment.

The regional appeals committee decided that the consultant in question had held a hospital staff appointment with full clinical responsibility since February, 1940 (when he resumed clinical work after the break occasioned by his administrative appointment). He was accordingly entitled to full seniority, and his starting salary was fixed at the maximum point in the scale as from July, 1948.

Heard at Headquarters**Night Calls**

The assembly of a number of rural and semi-urban practitioners in Essex at the opening of the Harlow health centre afforded an opportunity for inquiring how frequently the general practitioner was disturbed by a night call. It all depends on what is meant by a night call. If the regulation hours, 8 p.m. to 8 a.m., are taken, a different picture will be obtained, but if night calls are those which actually bring the doctor out of bed, say from midnight to breakfast time, one practitioner said that he had on the average one a week, another that he had one in ten nights; and that seemed to be about the level. The peak hour for calls was said to be the early evening, largely determined by the fact that the father comes home from work and finds the mother anxious about a child who had been ailing all day but hesitant about sending for the doctor on her own responsibility. Maternity cases, of course, alter the picture, and it was said that in this part of Essex about half the mothers are still confined at home.

Nagging Note

According to press reports, families may be given some housing priority at Newcastle-upon-Tyne if a doctor's note is produced showing that mother has nerve trouble because of constant nagging. But the domestic trouble has to be serious. According to a councillor, it will be no good just saying, "I've had a row with my in-laws. I want a house." A doctor, anticipating a prodigious demand, writes in to ask for some suitable certificate forms.

Questions Answered**Income Tax on Compensation**

Q.—*In Northern Ireland the Ministry of Health has made a payment of interest as at January 21, 1951, on compensation for loss of goodwill of medical practices. Income tax has been deducted at 9s. 6d. in the £, being the standard rate ruling at the date of payment, although the interest has been earned to some extent during a period when the standard rate of income tax was 9s. in the £. Can any adjustment be claimed in respect of this over-deduction of 6d. in the £?*

A.—Retrospective payments must rank for tax at the current rate (Section 39 (1) of the Finance Act, 1927). The date on which the interest on compensation will become due will presumably be the date on which the Minister of Health declares it to be due, and tax on the whole of the arrears will accordingly be deducted at the standard rate in force on that date.

Called Up

Q.—*I have been warned that I shall be called for 14 days' military training this summer. Am I entitled to make any claim to the War Office for the cost of a locum to do my work while I am away?*

A.—No. Neither the War Office nor the Ministry of Health undertakes the payment of the locum's fees in these circumstances.

Correspondence

Health Service Charges

SIR,—In your leading article on the Health Service charges (*Journal*, February 9, p. 312) you rightly refer to the difficulties of dispensing doctors, who will now become tax collectors. Quite apart from the natural distaste we will feel for the job, the greatly increased paper work, and the barrier between our patients and ourselves, many of us will be substantially out of pocket. I estimate that, in spite of notices and warnings, fully 20% of patients will come to the surgery without the necessary cash, and unless we institute a system of bookkeeping and accounts it will come out of our own pockets. In many cases this will involve the doctor in a loss of £30 to £50 per annum.

An anomalous position arises in the different methods of collection in the cases of doctors dispensing by tariff and those dispensing by capitation. The patients of the former pay their shillings, while those of the latter get their medicines free, or most of them. Where two doctors, using different systems, practise in the same area, as in my own case, the bewilderment of the patients may be imagined.

Apart from these considerations, in my opinion by far the most important aspect is the degrading and lowering effect it will have on the status of dispensing doctors. Most of us dispense for our patients because of our isolated situations, not because we want to. If we now have to collect a shilling at each consultation, find change, rattle cash-boxes and haggle over payment, each time becomes a sordid commercial transaction. I hope the B.M.A. will energetically resist this imposition in accordance with the resolution passed by the Annual Conference of Local Medical Committees.—I am, etc.,

Rolvenden, Kent.

B. W. WYLLIE.

SIR,—A very large number of doctors are behind the Government in the 1s. charge per prescription. It is most unfortunate, therefore, that the papers and the B.B.C. announced on February 13 that the B.M.A. or one of its Committees opposes it, without stating that their views are not those of the mass of the profession.—I am, etc.,

London, S.E.27.

F. H. HUNNARD.

SIR,—Your leading article in the *Journal* of February 9 (p. 312) is valuable in setting out the pros and cons of the proposed charge of 1s. for prescriptions under the N.H.S. The present excessive cost of medicines ought surely to be dealt with. Any pharmacist can show how medicines are still being ordered on E.C.10 which are expensive and could be either done without or replaced by less costly ingredients.

The increase in the number of proprietary preparations since July, 1948, is significant, and the authorities are not yet curtailing the prescribing of them as would be reasonable and essential. It would not matter so much if the profit from prescribing of proprietary medicines went into State funds, but it does not. The Minister of Health's words are, "The cost of medicines has risen enormously." The waste in prescriptions requires urgent attention.—I am, etc.,

London, N.W.11.

L. S. WOOLF.

SIR,—As one of the forgotten men of the medical profession, the dispensing doctor, I wish to make a strong protest against the new order requiring us to collect levies for the Government in order that a service which in its present form I have always been very much opposed to, but which, by the threat of what seemed to me to be very near to blackmail, I was forced to take part in, may be financially bolstered up and saved from utter collapse.

I am quite certain that my work will be greatly increased, as it was when we were told (not asked) to sort our own prescriptions owing to the "overworked condition of the pricing office." I can visualize the numerous arguments with

an already belligerent public—for example, the woman who has left her purse at home; the child whose mother will send up the shilling to-morrow; the person who does not think he should pay, as he already pays his stamp contribution; and so on. Do we refuse the medicine in these cases and risk the headlines in the Sunday scare sheets? Or are we expected to lose the shilling? Let the Government give a definite ruling on this and let us have printed posters which we can exhibit in our waiting-rooms.

What about the numerous patients living long distances away, with perhaps only one or two buses a day, which arrive at the surgery at times other than surgery hours? Now these medicines are put out for them during surgery hours and they collect them at times suitable to themselves. Perhaps they will now have to come in surgery hours and greatly swell the already overcrowded surgeries.

I note we are asked by the Ministry not to increase quantities on prescriptions and also not to put more than two items on one form. Do they think patients will pay 2s. for, say, three or four items because they are written on two forms? Let us have a directive, printed on an official poster, so that patients need not waste our time arguing with us and widening still further the growing chasm between patient and family doctor.

So far as I can see this is yet another order which has been rushed through without settling the details of the scheme, and again it is left to the doctor to sort things out and take all the extra work plus the kicks.—I am, etc.,

Dover.

E. T. MANLEY.

SIR,—You seem to be extraordinarily indifferent in your leading article (*Journal*, February 9, p. 312) to the way in which dispensing doctors have been made tax collectors overnight in spite of the declared opinion of the Annual Conference of Local Medical Committees. Does it not rouse you to anger? How long will it be before we all have to collect 6d. before giving advice? What urgent action is the B.M.A. taking in this matter? It is impossible to imagine a more clumsy piece of administration.—I am, etc.,

Amble, Northumberland.

R. P. ROBERTSON.

SIR,—With regard to the proposed tax of 1s. on every prescription, I see it has been suggested that the doctors should be made responsible for the collection of this charge.

It seems to me that it would be simpler to let every patient get 1s. Health postage stamps from a post office and affix one on the back of the prescription form. When the chemist has dispensed the prescription he could sign across the stamp.

All those who would be exempt from the charge could have their prescriptions on Form E.C.10 of a special colour. Perhaps these suggestions would simplify the collection of the tax and at the same time ease the doctors' work.—I am, etc.,

Guildford, Surrey.

GEORGE H. PEAKE.

SIR,—As to the B.M.A. statement on charges on prescriptions (*Supplement*, February 16, p. 61), I cannot imagine that the view expressed in any way represents the majority opinion of practitioners except so far as collection is concerned. "Financial barrier between doctors and those who need their services" forsooth, when the real barrier between the patients and adequate treatment is the abuse of the Service which this charge in the opinion of many would alleviate.

One hopes that no recommendation will be made to the profession without consulting the profession.—I am, etc.,

London, N.6.

W. L. TEMPLETON.

SIR,—I was amazed to see the objection raised by the B.M.A. to the shilling prescription charge (*Supplement*, February 16, p. 61). Surely a fee like this is the one thing which may keep down the insatiable demand for the useless "bottle of medicine" and the accompanying inevitable family consultation. Rather than a hardship, a shilling for a worthwhile prescription is a very good bargain indeed.

As for the collection of the fee, does not the request for a shilling or two for a certificate come in the same category? Yet the majority of doctors make this charge.

As it seems most unlikely under the present economic conditions that an increased capitation fee will be granted, it would appear the height of folly for the doctor's representatives to oppose a measure which will help to alleviate the burden on the busy practitioner and on the taxpayer simultaneously.—I am, etc.,

London, S.E.23.

IAN S. MACLEOD.

Supplementary Ophthalmic Service

SIR,—In answer to Dr. S. Chaplin's letter (*Supplement*, May 26, 1951, p. 216) in which he advocates legal action against the Minister of Health for the manner in which he reduced the Supplementary Ophthalmic Scheme fee from 25s. to 20s. last year, and has subsequently refused to pay the retrospective fee balance promised: I feel that it should be more generally known that the way the Minister got out of this difficulty was by including in the new fee of 20s. a moiety calculated against his legal obligation for retrospective payment, which he had promised before the inquiry on the time taken for refraction was set afoot.

I secured this information from a member of the Ophthalmic Group Committee only some two weeks ago when I discussed this same matter with him, and it seemed to me to preclude any such legal procedure. It is a pity that neither the Faculty of Ophthalmologists nor the Ophthalmic Group Committee troubles to provide a regular service of information to their members on such points of general ophthalmopolitical interest. This perhaps explains the general apathy evinced by ophthalmologists towards such matters when they are asked to do anything concrete about them from time to time. This is underlined by the appeal in the *Supplement* of February 9 (p. 51) to ophthalmologists to nominate representatives to sit on the ophthalmic services committees and in the past by appeals for nominations to the Council of the Faculty of Ophthalmologists. Perhaps we do not care any longer whether we die from the head downwards or the feet upwards.—I am, etc.,

London, W.1.

L. M. GREEN.

G.P.s' Access to X-ray Department

SIR,—There have been several articles in the *Supplement* recently on direct access by general practitioners to x-ray facilities—with some difference of opinion.

Free access to the x-ray department of Lewisham Hospital has been available to general practitioners and all surrounding clinics for over a year. This was tried out initially for a period of three months, and as it proved successful it was continued. The prime aim of this free access was to reduce the patient's waiting-time in the hospital. Previously cases referred by general practitioners for x-ray examination had to be seen by a medical officer in the receiving room, then referred to the x-ray department, and then back to the receiving room. Special request forms for use by clinics and general practitioners were carefully designed and printed in conjunction with the local Branch of the B.M.A. and distributed on request.

The upper part is for use by the general practitioner. The space for his address is of a size to accommodate a rubber stamp. He can also express a wish for his case to be referred or not to the appropriate department if considered necessary. All fracture cases are referred direct from the x-ray to the casualty department unless stated otherwise, and so also are all those traumatic cases whose wet films cannot be immediately seen by the radiologist. This ensures that fracture cases do not leave the hospital without being seen by a medical officer. Cases x-rayed in the forenoon usually have their report sent to the general practitioner on the same day.

Review of one year's "direct access" to the x-ray department shows that:

(1) Most local practitioners, clinics, and some dentists take full advantage of the direct access.

(2) About one-half of the practitioners make fuller use of the service than do the others.

(3) The practitioners usually give very good clinical information.

(4) Waiting-time spent in hospital by patients referred by general practitioners for x-ray examination has been very greatly reduced.

(5) This service does not appear to have increased the radiological work of the department during the year reviewed. General practitioners' cases amount approximately to 12% of the total work—that is, to about 12 cases a day. It is considered that most of these cases would have been referred to the hospital casualty or out-patient departments if there had been no direct service and would eventually have found their way to the x-ray department.

(6) Most of the ordinary x-ray examinations are carried out, including barium-meal examinations. Barium-enema examinations, however, are carried out after reference to out-patient departments to facilitate the necessary preparation.

(7) The waiting-list for barium examinations is shorter than that for medical or surgical out-patient departments. Cases referred for gastric and intestinal conditions may thus have the barium or other investigation completed before being seen by the consultant in the out-patient department. This is carried out in cases that will obviously require x-ray examination, and in this way some early cases of carcinoma of the stomach have been found without delay and immediate admission arranged.

(8) Practically no extra clerical work is incurred provided that practitioners utilize the forms supplied. A few practitioners cannot be so persuaded by request, and cause much extra clerical work.

(9) No abuse of the service apart from this has been noticed.

(10) The service is considered satisfactory by the local B.M.A. and by all practitioners who have been contacted from time to time.

(11) As mentioned in an article in the *Supplement* of February 9 (p. 50), it has brought about many useful and friendly relationships between radiologist and practitioner.

(12) The present acute shortage of x-ray films has restricted the radiological examination to a minimum and at times has caused postponement of all cases except absolute emergencies. Practitioners responded to our request to forward only really necessary cases, and but for this the total number received would probably have been much greater.—I am, etc.,

London, S.E.13.

MICHAEL WOOD.

POINTS FROM LETTERS

Employ Professionals

Mr. DONALD M. O'CONNOR (Launceston, Cornwall) writes: Your leading article, "Preparing the Case" (*Journal*, February 2, p. 263) pinpoints the cause of our present troubles and difficulties in a way which perhaps you did not intend. You wrote of "the negotiators—all busy men in medical practice." Does anyone seriously contend that the negotiations upon which depend the livelihood of twenty thousand practitioners and their families should be carried on as a spare-time hobby by men who are really busy in medical practice? Enthusiastic amateurism has finally muddled along to a position in which we must employ professionals who will, as you point out, be opposed by the best professional brains which can be mustered against us. One can only deplore the fact that the need to employ professionals was forced upon us and not recognized, as it should have been, and acted upon five years ago. . . . Your article makes much of the need for skilled preparation of a case designed to secure our rights to the tenth of a penny, and the point is indisputable, but, as I wrote in an earlier letter, we want help *now*. We need some sort of interim settlement which is based on the obvious and manifest fact that the figures which were foisted upon us in 1948 are inadequate in view of the increase in cost of living since that time. An increase of 20% in our net incomes would bring us into line with the wage-earners and would make life a vastly easier matter for many of us.

Association Notices

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1952 of prizes of the value of 20 guineas for the best essay, and 10 guineas for the second best essay, submitted in open competition by each of the following categories of nurses: (1) student nurses; (2) State-registered nurses working in a hospital; (3) State-registered nurses not working in a hospital (i.e., district nurses, private nurses, etc.); (4) State-enrolled assistant nurses.

The subjects of the essays for 1952 are:

Category 1.—"Why did you decide to take up nursing? Why do you think some nurses give it up?"

Category 2.—"What can be done to make the most efficient use of trained nursing staff in hospitals, with special reference to the avoidance of wastage?"

Category 3.—"Discuss the risks of conveying infection in the course of your work and the steps you would take to prevent it."

Category 4.—"The nursing care of the incontinent patient."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes *due regard will be given to evidence of personal observation*. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize.

Nurses who are undergoing a course of training at a hospital are eligible to compete under Category 1; nurses registered by the General Nursing Council are eligible to compete under Categories 2, 3, or 4, whichever is appropriate.

If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made.

The essay should be typewritten if possible, but a legibly written manuscript will receive equal consideration. It must be written in the English language, unsigned, and have attached to it a note containing the name and address of the candidate and the category into which he or she falls. Essays, which it is suggested should consist of 2,000 to 5,000 words, must be forwarded so as to reach the Secretary of the British Medical Association not later than March 31, 1952.

Preliminary notice of entry for this competition is required, and a special form for this purpose is obtainable from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Diary of Central Meetings

FEBRUARY

- 27 Wed. Compensation and Superannuation Committee, 11 a.m.
- 27 Wed. Committee on the Association of the General Practitioner with Hospital Work, 2 p.m. (*Date changed from February 20.*)

Branch and Division Meetings to be Held

BRIGHTON DIVISION.—(1) At Sussex Eye Hospital, Brighton, Wednesday, February 27, 3 p.m., clinical meeting. (2) At Hotel Metropole, Brighton, Saturday, March 1, 7.30 for 8 p.m., annual dinner. Principal guest, Dr. Charles Hill, M.P.

BURNLEY DIVISION.—At Sparrow Hawk Hotel, Burnley, Friday, February 29, 8.30 p.m., annual general meeting.

CITY DIVISION.—At Finsbury Health Centre, Pine Street, London, E.C., Tuesday, February 26, 8.30 p.m., Dr. Raymond Greene: "Endocrinological Treatment in Gynaecology."

COVENTRY DIVISION.—At Orthopaedic Clinic, 55, Holyhead Road, Coventry, Tuesday, February 26, 8.30 p.m., demonstration and discussion by Mr. J. H. Penrose: "Some Common Orthopaedic Conditions of Childhood."

FURNESS DIVISION.—At Orthopaedic Out-patient Department, North Lonsdale Hospital, Tuesday, February 26, 8 p.m., meeting of Barrow and Furness Clinical Society. Three films will be shown illustrating some aspects of accessible cancers. A discussion will follow.

HARROW DIVISION.—At Clay Pigeon Hotel, Eastcote, Wednesday, February 27, 8.30 p.m., general meeting. Discussion by Dr. E. Idris Jones and Mr. W. E. Springford: "Peptic Ulcer."

ISLE OF WIGHT DIVISION.—At Spencers Inn, Ryde, Saturday, March 1, 8 for 8.30 p.m., annual dinner. Annual B.M.A. Lecture by Sir Arthur Porritt.

LAMBETH AND SOUTHWARK DIVISION.—At Lambeth Hospital, Brook Drive, London, S.E., Sunday, March 2, 11 a.m., clinical meeting.

SALISBURY DIVISION.—At General Infirmary, Salisbury, Friday, February 29, 11.15 a.m., demonstration by Dr. J. G. Bourne: "Use of Cyclopropane instead of Nitrous Oxide for Dental Extractions."

SOUTH LANCASHIRE AND EAST CHESHIRE BRANCH.—Wednesday, February 27, 2.30 p.m., visit to Dobson's Dairies Ltd., Lloyd Road, Levenshulme, Manchester.

SUTTON COLDFIELD DIVISION.—At Sutton Coldfield Hospital, Friday, February 29, 9.15 p.m., ordinary meeting. Lecture by Professor Hugh C. McLaren: "The Cervix in Pregnancy."

TOWER HAMLETS DIVISION.—At St. Andrews Hospital, Devons Road, Bow, London, E., Friday, February 29, 3 p.m., clinical meeting.

WEMBLEY DIVISION.—At Wembley Hospital, Tuesday, February 26, 9 p.m., discussion to be opened by Dr. E. Grundy: "Recent Welfare Provisions."

Meetings of Branches and Divisions

SOUTH-EASTERN COUNTIES DIVISION

A meeting of the Division was held at St. Boswells on December 3, 1951. Present were Dr. A. Simpson (chairman), and Drs. McGregor, Weatherhead, Haddon, J. Henderson, F. Henderson, Glover, Anthony, Adam, McCracken, Martin, Yellowlees, Davidson, Clark, Smith, McLay, Rigby Lynn, Balfour, Grieve, and Duff.

Dr. Haddon gave the meeting an excellent report on the recent activities of the local medical committee. After that Dr. Weatherhead and Dr. Glover opened a discussion on the First Interim Report of Council on the Reform of the National Health Service. The former ably summarized the salient points of the report, especially as it affected this area, and the latter stressed the importance of the first five recommendations. Subsequent speakers gave their views (usually at length) on various other matters in the Report. On the whole the Division was in agreement with most of the report and its Representative received adequate direction on most points; for the rest, as a guide to his conduct, he was recommended to his discretion and his conscience.

HERTS PHARMACEUTICALS LTD.

In Para-nasal infections **ARGYROL** provides
physiological action
without CNS stimulation
or rebound congestion

● A return to normal function by the decongestive, demulcent and bacteriostatic actions of ARGYROL is achieved without the side effects and rebound so frequent with many vasoconstrictors. In the solution of para-nasal problems, the ultimate advantages of using ARGYROL are readily apparent.

The ARGYROL Technique

1. The nasal meatus . . . by 20 per cent ARGYROL instillations through the nasolacrimal duct.
2. The nasal passages . . . with 10 per cent ARGYROL solution in drops.
3. The nasal cavities . . . with 10 per cent ARGYROL by nasal tamponage.

Its Three-fold Effect

1. Decongests without irritation to the membrane and without ciliary injury.
2. Definitely bacteriostatic, yet non-toxic to tissue.
3. Stimulates secretion and cleanses, thereby enhancing Nature's own first line of defence.

Decongestion and Relief without Rebound ● Decongestion without Dysfunction
— the medication of choice in treating para-nasal infection

COMPOSITION :

ARGYROL is a colloidal preparation containing 20% silver combined with alkali-treated protein to give solutions with a silver ion concentration near 10^{-8} m, a pH near 9, and a particle diameter between $1 \cdot 10^{\mu}$ and $1 \cdot 10^{\mu}$ that of *Staphylococcus aureus*.

*Argyrol is a registered trade mark, the property of the makers A. C. BARNES CO. NEW BRUNSWICK, N.J.

CLINITEST—urine-sugar analysis set

TRADE MARK

Distinct colours
for
reliable readings

Doctors and patients can be sure of the reliability and simplicity of 'Clinitest' (Brand) Sets and Reagent Tablets. The most distinct colour scale, the easily recognisable colours of the test, give patients confidence in their readings, so reducing the number of unnecessary visits to doctors. This one-minute, no heating, copper reduction tablet test can be made easily even under travelling conditions.

A valuable instrument for the practitioner for routine sugar analysis, 'Clinitest' is the accepted test for the detection and control of glycosuria. Sets and refill bottles of tablets comply with official specifications for appliances and reagents which may be prescribed on form E.C.10.

R

For the effective
relief of

"Night Cough"

associated with acute and
Chronic Bronchitis

TERPOIN Elixir has long enjoyed high reputation with physicians throughout Great Britain and overseas for the effective relief it affords in all conditions of the respiratory tract characterised by excessive coughing. TERPOIN is presented in a palatable syrup base of bright golden colour and is well-tolerated and accepted by young and old. It is expectorant, mildly antiseptic, sedative and does not induce cerebral depression.

TERPOIN is thus indicated in the distressing and exhausting "night cough" so frequently associated with acute and chronic bronchitis, bronchial asthma and pulmonary tuberculosis. Alleviation is prompt and restful, recuperative sleep, so valuable in the treatment of such conditions, is ensured.

Clinical samples and literature
gladly, on request.

A wider margin of safety in INTRAVENOUS ANAESTHESIA

Important advantages of

'KEMITHAL' SODIUM

Thialbarbitone

TRADE-MARK

- Induction is smooth and rapid.
- Complications such as sneezing, coughing, excitement and tremors are rare.
- Tendency to laryngeal spasm is reported to be less than with thiopentone.
- Undue respiratory depression does not occur.
- Post-anaesthetic recovery is rapid, and vomiting, restlessness and protracted depression are most uncommon.

'Kemithal' Sodium is issued in ampoules of 1 and 2 grammes, with or without distilled water. Boxes of 5 and 25. Ampoules of 5 grammes, without distilled water. Boxes of 5.

In chronic ulceration it has been established by microbiological assay that during treatment with CIMLAC GAUZE there is a rapid rise in the amino acid content of the tissue exudate. The contribution of glycine and other essential amino acids increases cell proliferation, and CIMLAC GAUZE will be found a valuable adjuvant to rapid healing.

INDICATIONS: Varicose ulcers, burns, wounds, carbuncles.

FORMULA: Aminacrine Hydrochlor. 0.1%, Hexylresorcinol 0.1%, in a sterilized glyco-gelatin base.

PRESCRIPTION PACK: Carton containing 10 pieces $3\frac{1}{2} \times 3\frac{1}{2}$ ". Each piece separately heat-sealed and enveloped, with printed instructions for use.

A 'SECOND OPINION' UNNECESSARY

Doctors need no second opinion regarding the value of the Soundmirror Magnetic Tape Recorder in almost every branch of the profession.

Sensitive to every sound audible to the human ear, this new high-fidelity instrument enables you to make and play back immediately and as often as you wish, sound recordings of consultations, diagnoses, lectures, psychiatric data, reports, interviews—even surgery in progress. Soundmirror recordings are made on reels of inexpensive magnetic tape. A sound library of valuable recordings can be built up, or when desired old items can be erased from the tape and new recordings made.

Models from £69 10s., exclusive of microphone.

Dalmas Window Dressings

DALMAS window dressings have a central window through which operation wounds may be constantly observed at all stages of recovery. These dressings are sterile and remain sterile, and therefore can be applied in the theatre, over stitches and clips, immediately after the operation is completed.

They have adhesive margins at the side of the dressing. They may be sealed top and bottom with Dalmas waterproof strapping. There is no dragging of stitches or clips. The elastic properties of this dressing enable it to be moulded to the body contours.

The protective gauze covering is treated to ensure sterility, despite exposure to the air over several weeks. The residual antibacterial properties of the film help to inhibit the growth of organisms in the wound area. A group of eminent surgeons report that during a six-month period when Dalmas window dressings were used on 300 surgical cases, not a single case of sepsis arose.

Dalmas window dressings can be cut to fit a particular incision. And as they are waterproof, patients can be washed without inconvenience. They are cheaper to use than normal dressings, since they can be left in position over long periods.

In order to allow adequate aeration of the wound, and to prevent accumulation of moisture, it is usually desirable to leave the top and bottom of the dressing unsealed. In special cases where complete sealing is indicated, the top and bottom of the dressing may be closed by the application of Dalmas waterproof strapping.

Dalmas window dressings may be obtained direct from Dalmas Limited, Leicester, or through your usual supplier. They come in the following sizes:— 8" x 3", 8" x 4½", 16" x 4½", 12" x 3", 36" x 4½", 36" x 3".

Samples and literature available to interested practitioners. Special terms for hospitals.

SUCCINATE-SALICYLATE THERAPY

Licensed under DOLCIN Patent. Patented in Great Britain 642971

IN TABLET FORM

For the relief of symptoms and
aid in the control of the systemic metabolic
disturbances found to be associated
with Arthritis and all Rheumatic
disorders

INDICATIONS

1. Rheumatic Fever.
2. Articular Rheumatism
(including Rheumatoid and
Osteo-Arthritis).
3. Non-Articular Rheumatism
(including Fibrositis, Neuritis
and Sciatica).
4. Arthritis associated with the
menopause.
5. Gout.

FUNCTION

A stimulating effect
on cellular respiration and
respiratory enzyme systems,
together with an increase of
oxygen utilisation by the
tissues (impairment in tissue
oxygenation having been
demonstrated in Arthritis).

Since **BEREX** is NON-TOXIC it may be prescribed
whenever massive salicylate therapy is indicated.

BEREX combines the following advantages: Prompt
relief of symptoms; correction of impaired tissue oxida-
tion; obviation of salicylate toxicity; suitability for
protracted administration.

ANY QUESTIONS?

FOR EIGHT YEARS a number of experts have each week constituted a Brains Trust for answering questions sent to the *British Medical Journal* from all over the world.

"ANY QUESTIONS?" is a current guide to the practice of medicine. Many of the authoritative answers given supply practical information not yet in the textbooks.

THE BEST of "Any Questions?" is now offered in book form. Please reserve your copy as the edition is limited. The book is bound in cloth, fully indexed, small enough to fit the pocket, and quite indispensable to the General Practitioner in his daily work (pp. 268).

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent★ testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR:** Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR:** Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER:** £350 per annum for the first post held; £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER:** Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER:** Officers who have held house appointments but who are not Registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.
